## FOREWORD

Weeds are one of the major factors impacting on Australia's biodiversity and agriculture. Weeds change the functioning of natural ecosystems, compete with and alter the habitat of native plants and animals and even threaten the survival of some species that are in low numbers. Weeds also impact negatively on agriculture by increasing costs either by interfering with crop growth or animal production or by acting as harbours for pests and diseases of agricultural plants.

Introduced plants that have become naturalised in Australia now comprise about 10% of the total Australian flora. They include many plants that were introduced intentionally for agriculture and horticulture.

Not all introduced and naturalised plants necessarily become invasive, although many do. This book aims to categorise the approximately 2700 non-native plant species that are known to be naturalised in Australia into groups of major or minor threats to natural ecosystems or agriculture. Some non-native naturalised plant species present in Australia are known to be weedy overseas and may have similar effects here. Some of these are recommended as targets for eradication programs because eradication could be achieved at relatively low cost before they become invasive and spread widely.

The categories of non-native naturalised plants highlighted in this book thus suggest opportunities for future containment and eradication programs. This categorisation of Australia's naturalised flora will be a useful resource for those involved in weed management, and those involved in natural resource management more broadly.

## S U M M A R Y

The naturalised flora of Australia was compiled from vouchered specimens in State, Territory and national herbaria. It was found to consist of about 2700 species believed to be non-native, although some uncertainty remains about the introduced status of a small percentage of that total.

Of this total, 798 species (about 30%) were considered a major problem and 1388 species (about 50%) a minor problem to managers of natural ecosystems. A total of 34 non-native species that are limited at present to one or a few populations in a defined geographic area is recommended for eradication from natural ecosystems. Those non-native species known to be having a direct impact on rare or threatened native plants numbered 49; most of these species are widely distributed across a number of States but 8 within this group with more limited distributions are suggested as further candidates for eradication from natural ecosystems.

The majority (53%) of Australia's naturalised non-native species were considered to pose little or no threat to agricultural ecosystems. Of the total of 1266 species that were considered a problem, 840 (about 65%) were categorised as a minor problem only, partly because they were not considered sufficiently important to warrant control at any location. Species that may act as harbours for diseases or insect pests, or that may be toxic at some stage of their life cycles, numbered 295. Sixteen naturalised non-native species were known to be subject currently to eradication attempts throughout their known Australian range because of their perceived impacts on agricultural ecosystems. A further 9 species are suggested as candidates for eradication from agricultural ecosystems.

For nearly all the plant species considered, information on their dates of naturalisation, their likely rates of spread, or their likely economic impact was not available. These deficiencies in knowledge will need to be overcome before predictions of the probable negative impacts of weeds on Australian natural and agricultural ecosystems can be further refined.

The work presented in this book was commissioned by the Department of Environment and Heritage and the Bureau of Rural Sciences in 2000 and 2001 respectively. The Cooperative Research Centre for Australian Weed Management convened a group of scientific experts on weeds and the Australian flora from all of the States and Territories of Australia to undertake the projects. This book represents a combination of the previously unpublished reports which resulted from these two projects. An addendum (page 14) briefly describes developments since the original reports were written.

## INTRODUCTION

A range of different categories and terms may be used to describe non-native plants, depending on what stage of the overall invasion process they are at, which in turn is determined largely by biological characteristics and introduction history. Naturalised non-native plant species may be defined as those that have been introduced, become established and that now reproduce naturally in the wild, without human intervention. This definition combines two of the current usages recognised recently by Richardson *et al.* (2000). Collectively, this category of the total number of plant species in Australia is termed the naturalised flora. Some categories of naturalised non-native plants already are well defined because they have legal standing; other categories are less well defined.

The special category of 'noxious weed' is recognised throughout Australia, in that the category is enacted by legislation in each State or Territory for particular invasive plant species. Not all 'noxious' plants, however, are declared for every State or Territory. For instance, an invasive plant species of the wet Tropics may be declared 'noxious' in Queensland, the Northern Territory and for the northwest of Western Australia, but not in the temperate southern states in which the species' chances of becoming invasive may be low or non-existent. Wherever it is enacted, a declaration of 'noxiousness' always implies the need for active management to reduce the impact of the particular plant species on human activities. Declaration of invasive plant species has a long history in the Australian States. Often in the past, however, noxious plants were widespread and already abundant in the landscape before they were declared and very little may have been done subsequently to reduce their populations (Moore 1971). Accordingly, recent emphases with regard to this category of naturalised plants have shifted to consider smaller scales of distribution (e.g. a catchment) and different sub-categories of 'noxiousness' on which land managers can be seen to act.

To address goal 2 in the National Weeds Strategy (Anon. 1999) 20 invasive plant species, with mostly widespread distributions in Australia, were categorised and accepted as the Weeds of National Significance (WONS). The technical criteria behind this category are described in Virtue *et al.* (2002).

Some other categories of naturalised non-native plants are less well defined; they include plant species that are categorised as introduced and/or adventive – terms that encompass plant species known to be native to a region or regions outside Australia. Such a category may also be termed variously alien or exotic. Of the total number of introduced species that have been detected only relatively recently in Australia (i.e. within the last 15 years or less), a small number (relative to the total) that are known already to have major negative impacts on natural or agricultural ecosystems outside Australia, are categorised as Recent Incursions. These plant species may receive special consideration nationally, that leads to the development of an appropriate management strategy such as eradication or containment.

A category of naturalised non-native plant species that has been recognised only very recently is that of so-called 'sleeper weeds'. This category has been defined as those non-native plants that have naturalised but are believed to have not yet reached their potential to form large and widespread populations in Australia (Groves 1999), despite being naturalised for some years. Like the category of Recent Incursions it is an attractive category for action because the cost of containment or of eradication expended now is much less than the relatively high future costs when the species has spread and reached its ecological limits (Williams 1997).

Another term that has arisen relatively recently in Australia is that of 'environmental weed'. This term refers to those naturalised non-native plant species that have invaded non-agricultural areas of natural vegetation and are presumed to impact negatively on native species diversity or ecosystem function. This category may also consist of plant species that are invasive beyond their native or indigenous range – a further complication and one that is becoming more significant as Australian

plants are used more widely in both horticulture and re-vegetation projects within Australia. Environmental weeds are distinguished from agricultural weeds by the ecosystem they impact in some way but it should be noted that the one plant species may be invasive in both natural and agricultural ecosystems in Australia.

Whilst there exist different criteria for the definition and use of these terms for different categories of naturalised plant species that are non-native to Australia, the terminology used to describe the conservation status of native plant species is usually defined much more rigorously. Australia follows the IUCN criteria for the different categories of rarity (see, for example, Briggs and Leigh 1996). These criteria are included in the most recent database for threatened plants native to Australia – the Species Profile And Threats database or “SPRAT” – maintained by the Department of Environment and Heritage. The SPRAT database lists endangered or vulnerable plant species for Australia (usually termed Rare Or Threatened Australian Plant, or ROTAP, species and now listed under the *Environment Protection and Biodiversity Conservation Act, 1999*). The database identifies threats to these species, although the threat posed by naturalised species is usually a general one and the particular non-native species responsible for the threat only sometimes are identified.

This book groups Australia's total of about 2700 naturalised non-native plant species into categories; some of the above categories will not be discussed further, such as the WONS group. The first part of the book concerns the categorisation of the species comprising the naturalised flora based on their perceived negative impacts on the approximately 25,000 native plant species and especially on those that are listed as endangered or vulnerable. It will identify some naturalised non-native species (so-called environmental weeds) considered of greatest threat to native plant diversity in the short term that may still be amenable to early intervention. The second part of the book groups a slightly up-dated listing of naturalised non-native species into categories based on their perceived impacts on Australian agricultural ecosystems. This part of the book will identify a further number of species of agricultural weeds, including some in the ‘sleeper weed’ category, as candidates for early intervention leading to their containment or eradication from Australia.

The work presented here was commissioned by the Department of Environment and Heritage and the Bureau of Rural Sciences in 2000 and 2001 respectively (see Appendices 1 and 2). The Cooperative Research Centre for Australian Weed Management convened a group of scientific experts on weeds and the Australian flora from all of the States and Territories of Australia to undertake the projects. This book represents a combination of the previously unpublished reports which resulted from these two projects.

## METHODS

### GENERAL

A listing of all naturalised non-native plants in Australia (Hosking *et al.*, in prep.) was made available as a database of about 2700 taxa. The total number of non-native naturalised species used to assess categories applicable to natural ecosystems was 2681, (see Appendix 3) at the time the first categorization was done in 2000. The categorisation of Australia's non-native naturalised species for their potential agricultural impact was done one year subsequently and hence the total number of species was slightly increased (at 2732 taxa), as a result of continuing research and updating of nomenclature (see Appendix 4).

A limited number of species are considered to be 'native' by some State herbaria but 'introduced' or 'non-native' by other State herbaria (see Table 1 and Appendix 3 for examples). From this national list, a separate database for each State or Territory was created. The only species to be considered throughout this book were ones for which a voucher specimen existed at a State, Territory or the National herbarium. Such a proviso means that all names used in this book can be checked should queries arise in the future. Species listed on each State database were then ranked in terms of an agreed set of categories appropriate to either natural or agricultural ecosystems, details of which are given in the next two sections respectively. The rankings were made by experts from each State or Territory and represent the best personal judgements available.

In each case when assembling the national rating from the individual State and Territory ratings, the highest rating by any one State or Territory was used. The ratings for each species were then tabulated and the total scores for the number of species in each of the different categories added.

The total number of species considered appropriate for containment and/or eradication was further reduced by asking each expert who made the initial rankings to choose the one or two species they considered most suitable for eradication from their State or Territory. Two national listings of these species were then compiled: one for naturalised species that pose a direct threat to natural ecosystems because of their perceived impact on endangered native plant species; and the other on the basis of the perceived potential of naturalised species to impact agricultural ecosystems in the future, should they ever spread further.

Throughout the book, we shall refer to each taxon as a 'species', even though this usage does not always reflect its true taxonomic status.

### NATURAL ECOSYSTEMS

The agreed categories for assessing the status of naturalised non-native species in natural ecosystems were:

**Category      Explanation**

- |    |  |
|----|--|
| 0  | Reported as naturalised but only known naturalised population now removed or thought to be removed                 |
| 0? | Uncertainty as to whether any plants exist   |
| 1  | Naturalised and may be a minor problem but not considered important enough to warrant control at any location      |
| 1? | Uncertainty as to whether a small number of plants remain  |
| 2  | Naturalised and known to be a minor problem warranting control at 3 or fewer locations within a State or Territory |

- 3 Naturalised and known to be a minor problem warranting control at 4 or more locations within a State or Territory
- 4 Naturalised and known to be a major problem at 3 or fewer locations within a State or Territory
- 5 Naturalised and known to be a major problem at 4 or more locations within a State or Territory
- ? Information not available at present.

Categorisations were carried out in 2000 for naturalised plants of natural ecosystems. Other attributes were used to further categorise the national listing (see Appendix 3). They were:

<i>Symbol</i>	<i>Explanation</i>
C or c	Under active control throughout State (C) or in part of State (c)
E or e	Eradication being attempted throughout State (E) or in part of State (e)
N or n	Noxious and/or Declared throughout State (N) or in part of State (n)
P	Proposed candidate for attempted containment or eradication
H	Habitat-specific
A	Agricultural and/or ruderal weed primarily; no known threat to native plants
S	Potential to spread further
Ø	Origin uncertain – possibly a native species according to some State herbaria.

## A G R I C U L T U R A L   E C O S Y S T E M S

Agricultural ecosystems were considered to be crops, pastures and horticultural enterprises such as nurseries and turf farms. Aquatic weeds (even those that may block irrigation channels or dams) were not included in this survey, nor were weeds of forestry. Species that have burrs on otherwise useful plants or those plants that rarely come into contact with stock also were not included.

The agreed categories for assessing the status of naturalised non-native species in agricultural ecosystems were those as for natural ecosystems (see above) with the following additions:

<i>Category</i>	<i>Explanation</i>
+	Present in a State or Territory but not given a rating as an agricultural weed, either because it was not considered a problem or because it was not known to occur in agricultural areas at present.

<i>Symbol</i>	<i>Explanation</i>
D	Harbour for diseases (potential or actual)
I	Harbour for insects that cause problems to agriculture (such as fruit fly)
T	Toxic (includes species that are toxic at times and useful at other times)
X	Includes weeds that potentially will be a greater agricultural problem than the rating shown; this category includes weeds presently known only from natural ecosystems.

These categorisations were carried out in 2001 (i.e., one year later than for those of natural ecosystems).

## R E S U L T S

### TAXONOMIC ASPECTS

The listing of all naturalised non-native plants for Australia is presented at Appendix 3, arranged alphabetically by genus and species. Alternate names are given where known. Of the 2681 species identified in Appendix 3, 34 were considered to be native by some State herbaria (Category Ø). Each of these problematic species is identified in Appendix 3 but they have also been listed (Table 1) to draw attention to the differences in taxonomic opinion.

**TABLE 1** The 34 plant species in the Australian flora about which there is uncertainty with regard to whether the species is native or naturalised; all species listed below are considered to be native by at least one State herbarium and to be naturalised non-native species by other herbaria.

Genus	Species	Family	Genus	Species	Family
Acacia	farnesiana	Fabaceae (Mimosoideae)	Lysimachia	vulgaris	Primulaceae
Adenanthera	pavonina	Fabaceae (Mimosoideae)	Lythrum	hyssopifolia	Lythraceae
Aeschynomene	aspera	Fabaceae (Faboideae)	Lythrum	salicaria	Lythraceae
Aeschynomene	indica	Fabaceae (Faboideae)	Mollugo	verticillata	Aizoaceae
Albizzia	lebbeck	Fabaceae (Mimosoideae)	Oryza	rufipogon	Poaceae
Bidens	pilosa	Asteraceae	Paspalum	distichum	Poaceae
Bromus	arenarius	Poaceae	Paspalum	scrobiculatum	Poaceae
Cenchrus	caliculatus	Poaceae	Pennisetum	alopecuroides	Poaceae
Chamaecrista	nigrigans	Fabaceae (Caesalpinoideae)	Persicaria	lapathifolia	Polygonaceae
Corchorus	aestuans	Tiliaceae	Phyla	nodiflora	Verbenaceae
Corchorus	capsularis	Tiliaceae	Pistia	stratiotes	Araceae
Crotalaria	retusa	Fabaceae (Faboideae)	Ruschia	tumidula	Aizoaceae
Cyclocarpa	stellaris	Fabaceae (Faboideae)	Russelia	equisetiformis	Scrophulariaceae
Cyperus	compressus	Cyperaceae	Salsola	kali	Chenopodiaceae
Echinochloa	colona	Poaceae	Sida	pusilla	Malvaceae
Ipomoea	nil	Convolvulaceae	Triumfetta	rhomboidea	Tiliaceae
Isachne	pulchella	Poaceae	Urena	lobata	Malvaceae

### Categorisation for natural ecosystems

Full details on the total numbers of species in each category for natural ecosystems are presented for each species in Appendix 3. Of the total of 2681 naturalised non-native species listed (Appendix 3), only 29 (Category 0) are known to have been eradicated, or thought to have disappeared, in the wild in Australia (Table 2), with a further 2 species of uncertain status in this regard (Category 0?). About half the total number of naturalised non-native species were judged to be a minor problem in Australia at present (Categories 1, 1?, 2 and 3). Of the 798 species that were considered a major problem, about 60% were known to be a problem at three or fewer locations (Category 4). The naturalised status of only 15 species (0.5% of the total) was unknown (Category ?), although future information may reduce this already low number still further.

**TABLE 2** Number of naturalised non-native species in the Australian flora categorised in 2000 in terms of their different stages of naturalisation in natural ecosystems (see Methods for explanation of these categories).

Category	0	0?	1	1?	2	3	4	5	?
No. species	29	2	431	18	676	712	465	333	15

The 731 species that were rated as primarily agricultural or ruderal weeds (Category A) were assumed to pose a lesser, or no known threat, to native plants (Table 3). A further 201 species were rated as habitat specific (Category H). In 2000, there were 437 species considered to be under active control (C or c category) or declared noxious in at least one State (Category N) or in part of a State (Category n). A total of 34 species were considered controllable or merited controlling, i.e. they belonged to Category P, and these individual species are recommended as candidates for attempted containment or eradication (Table 4). The collection of additional information could increase the number of species (presently 250 or c. 9% of the total) predicted to have potential to spread within or between States (Category S).

**TABLE 3** Number of naturalised non-native species in the Australian flora categorised in 2000 in terms of their status as weeds of natural ecosystems, their ability to be controlled or eradicated, and their potential for further spread (see Methods for explanation of these categories).

Category	A	H	C,c,N,n	P	S
No. species	731	201	437	34	250

Those species deemed appropriate for an attempt at containment or eradication are listed separately (Table 4), together with their distributions by State and/or Territory.

**TABLE 4** The 34 naturalised non-native species in the Australian flora that are impacting on natural ecosystems for which a national containment or eradication program is recommended, together with their distribution by State or Territory (see Addendum, page 14).

### Categorisation for impacts on Rare Or Threatened Australian Plant (ROTAP) species

A total of 49 naturalised non-native species were known to be having a direct impact on those native species rated as 'rare' or 'threatened' in the Australian flora (Table 5). They belong to a wide range of plant families. Many other naturalised non-native plants may also be having an impact on native plant and/or animal species but the effects were either not known to the authors or were considered to be indirect.

**TABLE 5** The 49 naturalised non-native species in the Australian flora having a direct impact on ANZECC-rated rare or threatened native plant species, together with their distribution by State or Territory.

Genus	Species	Subspecies (ssp.) or Varieties (var.).	Distribution	Genus	Species	Subspecies (ssp.) or Varieties (var.).	Distribution
<i>Anagallis</i>	<i>arvensis</i>	red & blue fl'd forms	All (not NT)	<i>Juncus</i>	<i>capitatus</i>		All

### **Categorisation for agricultural ecosystems**

Of the 1267 naturalised non-native species identified as a problem to Australian agriculture, about two thirds were considered to be of only minor importance at present (total of Categories 1, 2 and 3) (Table 6). Of the 426 species that were considered a major problem to agricultural enterprises, about 18% were known to be a problem at three or fewer locations (Category 4).

**TABLE 6** Number of naturalised non-native species in the Australian flora categorised in 2001 in terms of their different stages of naturalisation in agricultural ecosystems (see Methods for explanation of categories).

Category	+	0	0?	1	2	3	4	5
No. species	1444	6	15	353	133	355	64	362

In 2001 there were 429 species considered to be under active control (C or c category) or declared noxious in at least one State (Category N) or in part of a State (Category n) (Table 7 and Appendix 4). Eradication was being attempted throughout a State (Category E) or in part of a State (Category e) for 156 species. Species known to act as harbours for disease agents or insect pests numbered 31, and 264 species were identified as being toxic. Species proposed for control or eradication (Category P) numbered only 8 (see Table 8). Although virtually all species have the potential to spread further, 224 species were considered to have potential to spread considerably (Category S). A further category (X) comprised 108 species that are unlikely to have a greater agricultural impact than the suggested rating and includes species that at present are known only from natural ecosystems (Table 7).

**TABLE 7** Number of naturalised non-native species in the Australian flora categorised in 2001 in terms of their status as weeds of agricultural ecosystems, their ability to be controlled or eradicated and their potential for further spread (see Methods for explanation of categories). Species that may harbour diseases (actual or potential) or insect pests or are known to be toxic at some stage of their life cycles are also given.

Category	C,C,N,n	E,e	D,I	T,T?	P	S	X
No. species	429	156	31	264	8	224	108

Some of the species being eradicated throughout their Australian range at present or recommended as suitable for an attempt at their containment or eradication nationally are listed in Table 8, together with their distribution by State or Territory. Of the 16 species identified as currently subject to an eradication program, *Bassia* (*Kochia*) *scoparia*, *Centaurea maculosa*, *Jarava plumosa* (syn. *Stipa papposa*) and *Orobanche loricata* may already have been eradicated, although monitoring for all four species should continue for several more years to validate this apparent result. Programs for the remaining 12 species continue.

**TABLE 8** The 27 naturalised non-native species in the Australian flora that are impacting agricultural ecosystems for which a national or State containment or eradication program is being implemented or is recommended (based on information available in 2001), together with their distribution by State or Territory.

Genus	Species	Subspecies (ssp.) or Varieties (var.)	Distribution	Genus	Species	Subspecies (ssp.) or Varieties (var.)	Distribution				
<b>For eradication or being eradicated at present</b>											
<i>Asystasia</i>	<i>gangetica</i>	ssp. <i>micrantha</i>	NSW	<i>Nassella</i>	<i>charruana</i>		Vic.

## D I S C U S S I O N

### S P E C I E S T H A T A R E P O S S I B L Y N A T I V E

It is recognised widely that some cosmopolitan species in the Australian flora may be considered 'native' by some and 'introduced' by others. Kloot (1984) discussed the role of long-distance dispersal in influencing the introduced elements of the flora of southern Australia. He concluded that there were about 100 species that were believed, at least by earlier botanists, to have arrived in Australia from elsewhere by long-distance dispersal at a time that pre-dates European settlement (1788). These 100 or so species thus could be interpreted as either 'native' or 'introduced', depending on the time and means of introduction.

Furthermore, some plant species in what Kloot called his 'alien acquired' category may have a variant in Australia that is native and other variants that may have been introduced. Such taxonomic variation is especially true of naturalised species, such as *Tribulus terrestris*, where it is believed that a non-native variant or genotype occurs in southern Australia but that the variant or genotype common in central and northern Australia may be native (Squires 1969, Morrison and Scott 1996a, 1996b, Scott and Morrison 1996). It thus should come as no surprise that we identified a group of 34 species (Table 1), albeit a relatively small number of species, about which there is still some disagreement as to whether they are naturalised or native. This situation is highlighted by the example of one species listed in Table 1, viz. *Pistia stratiotes*, that is a noxious weed in all Australian States (where its control is obligatory) but the same species is considered native to the Northern Territory (Gillett *et al.* 1989). Only further research at an international level may resolve such uncertainties and seeming anomalies.

### I M P A C T S O N N A T U R A L E C O S Y S T E M S

This present categorisation of the naturalised non-native flora of Australia attempts to reduce the approximately 10% of the total Australian flora to smaller groups, and thereby draw attention to species which may be candidates for active management, leading in some cases to their eradication. Previous attempts, such as the increasingly-cumbersome system of State declarations of some non-native species as noxious, have focused management primarily on already-widespread species that have a predominantly agricultural impact. More recently, the recognition of twenty weeds of national significance has focussed management by community groups on a group of mostly already widespread 'environmental weeds' as well as agricultural weeds. Most previous declarations of 'noxiousness' have failed in the past, however, to direct management activity to those species that may not yet be distributed widely or are not yet having a major impact on production agriculture. Many such species are still only locally distributed and amenable to containment, if not eradication. Of the approximately 2700 species judged by us to be naturalised and non-native, we identified 34 species (Table 4) where we believe a containment or eradication program is feasible and justified ecologically in terms of their impacts on native plant species or natural ecosystems. We suggest that at least one species per State or Territory be targeted for eradication from natural ecosystems as a matter of urgency. For instance, *Succowia balearica* in Western Australia is an ideal candidate for early eradication before it becomes a major weed of the botanically-diverse natural vegetation on the Swan Coastal Plain (Keighery 1996).

In the national compilation of each State categorisation, we encountered several methodological problems to do with interpretation of categories, especially those relating to prediction of spread (Category S in Table 3). Sometimes species were known to be present in a State from personal observation but if that knowledge was not backed up by voucher specimens deposited in herbaria, we rejected it as a record in the national database, on which these categorisations are based.

A previous consideration of the naturalised non-native flora of Australia in terms of impacts on natural ecosystems (Humphries *et al.* 1991) concluded that whilst major weed problems in northern and central Australia usually arose because of invasions of single dominant species (e.g. *Cryptostegia grandiflora*, *Mimosa pigra*, *Tamarix aphylla*), those in southern Australia comprised groups of species. Many areas of natural vegetation in southern Australia have been invaded by many different non-native species with diverse life-forms and dispersal mechanisms. Management of such invaded vegetation based on a single-species approach usually results in one weed being replaced by another. An approach to research and management based on single species is implicit in the approach taken in the present short-term study, but it may not be effective for natural ecosystems in the longer term unless it is strengthened further by re-vegetation programs that use competitive but non-invasive native species.

### **IMPACT ON NATIVE RARE OR THREATENED AUSTRALIAN PLANT (ROTAP) SPECIES – A SPECIAL CASE**

Leigh and Briggs (1992) showed that four native plant species had become extinct because of presumed competition from weeds. A further 12 native species were endangered currently by the presence of non-native species, but 57 (13%) of the total of 441 rare or threatened native plant species were at risk in the future because of weed competition. Of the latter group, Groves and Willis (1999) highlighted two examples of a direct impact of naturalised non-native species on native plant diversity. The first related to the orchid *Pterostylis arenicola* endangered in South Australia by dense cover of the invasive South African species *Asparagus asparagooides* (Sorensen and Jusaitis 1995). In this example, the non-native plant was shown to have a direct negative impact on orchid rosette numbers. The second example is that of a small shrub *Pimelea spicata*, once widespread in southeastern New South Wales but now confined mostly to small fragments of Cumberland Plain woodland – itself an endangered community. In this example, the non-native plant is again *A. asparagooides* that shades the small shrubs of *P. spicata* in winter and competes with them for water and soil nutrients. The results of these two studies provide useful material on which to base management actions. They both concern one non-native species on our list of 49 that is impacting directly on rare or threatened native plant species. Research programs on some of the other 48 non-native plant species listed in Table 5 are urgently required. There are undoubtedly other rare and endangered species being impacted either directly or generally by naturalised plant species than the 49 identified in this study (for instance, see Halford 1998 and Anon. 2000 for southeastern Queensland).

### **IMPACTS ON AGRICULTURAL ECOSYSTEMS**

About half (53%) of the total naturalised non-native flora was considered to pose little or no risk to agricultural ecosystems, either because the species were not considered a problem in any State or Territory or else they were not known to occur in agricultural ecosystems at present (Table 6). Of the 1266 species considered to pose a problem to agricultural ecosystems, about 65% of them were categorised as only a minor problem at present, sometimes because they were not considered important enough to warrant control at any location. Such a rating may well change with changed patterns in agriculture, however. For instance, the silver grasses (*Vulpia* spp.) switched in the 1970s from being regarded as minor weeds to those having major impacts on agriculture in southern Australia.

Most of the species identified as major problems were known to occur at four or more locations – a fact that makes their eradication or containment all the more difficult. Only 64 species that were categorised as ‘major’ problems occurred at three or fewer locations in a particular State or Territory (Table 6). For instances where such species are known only from one State or Territory within the Australian region, a strong case could be made for increased management effort. Examples of such candidate species for eradication or containment are listed in Table 8, as a basis for further examination and possible future funding programs.

Our analysis of the naturalised non-native flora of Australia has highlighted 156 cases where eradication attempts are being made either throughout a State or in part of a State (Table 7). More needs to be known about the success of these efforts and the range of methods used, especially as they relate to the area covered by each population, the number of populations and the length of the post-eradication monitoring period. Recent results from California (Rejmanek 2000) indicate that the eradication of non-native plants from infestations smaller than one hectare in area is almost always possible, but that it is unlikely that infestations larger than 100 ha can ever be eradicated, given a realistic level of resources. Groves and Panetta (2002) assembled case histories for a limited number of past and current weed eradication programs in Australia, but more case histories will be needed before useful generalisations can be formulated. In this book we have highlighted 16 naturalised non-native species where nationally or State-coordinated eradication programs are being practised already; a further 9 are suggested as being highly appropriate and timely (Table 8).

One impact of naturalised plants that is often overlooked in discussions on weed impact is the role that such species may play as harbours for diseases or insect pests. Together with those plants that are toxic to animals or humans, they numbered 295 species (Table 7). Most had a wide distribution, however, and their eradication was usually considered to be not feasible. This aspect of impact on agricultural ecosystems encompasses some naturalised plants that are usually considered to impact on natural ecosystems, such as *Cotoneaster* spp., but which may also impact horticultural industries because they can act as alternate hosts for pathogens (such as fireblight in the case of *Cotoneaster*).

#### F U R T H E R I N F O R M A T I O N N E E D S

Whether for natural or agricultural ecosystems, spread rates for only a few naturalised plants are known and this paucity of information made it difficult to categorise the naturalised flora according to rate of spread, despite this attribute being related to invasive ability. The database used for these analyses did not include dates of naturalisation and this deficiency precluded consideration of the incidence of 'sleeper weeds' in the naturalised flora. Incorporation of dates of first collection (and perhaps number of sites) as a very approximate surrogate for the date of naturalisation into the database would enhance its usefulness in this regard, as would further research on which naturalised species may be usefully considered as 'sleepers' among both environmental and agricultural weeds. Given, however, the observed contribution of changed management regimes to increased impacts of agricultural weeds (see our earlier *Vulpia* example), the process of identification of 'sleepers' in an agricultural context may differ from that used to identify this category of naturalised species in natural ecosystems.

Finally, even for long-naturalised plants in agricultural ecosystems, let alone those primarily invasive in natural ecosystems, information on their likely economic impacts was rarely available. The main attribute of a plant species recently naturalised in Australia that seems to drive an eradication program is its known occurrence as a major weed outside Australia. An enhanced methodology for determining the likely economic impact of a recently naturalised species will need to be developed before prediction of the impact of such species on Australian natural and agricultural ecosystems can be further improved.

## A C K N O W L E D G M E N T S

We acknowledge the assistance of staff of many herbaria in the preparation by John Hosking of the database on all naturalised plants in Australia. We also thank Cathy Miller, Peter Moore, Kim Navin (CSIRO Plant Industry, Canberra) and David Cunningham (BRS) for help with the preparation of the Appendices; and Alan Maguire (NSW Agriculture, Tamworth), John Weiss (KTRI, Frankston) and Mark Boersma (DPIWE, Devonport) for information on noxious plants in New South Wales, Victoria and Tasmania respectively. Information on noxious plants for Queensland, Western Australia and the Northern Territory was obtained from the Weeds Australia web site at <http://www.weeds.org.au/>. Information on certain species for eradication was taken from a forthcoming publication by Geoff Sainty and others; we thank the authors for their permission to use their material in this way. David Cunningham, Dane Panetta and Peter Williams provided useful comments on a final draft of this book for which we are grateful. We thank Gerry Maynes and Robert Moore (DEH) and Mary Bomford (BRS) for initiating and guiding the two consultancies.

## A D D E N D U M

As of May 2003, the number of plant species in the naturalised non-native flora of Australia totalled 2810 – an increase on the totals presented in the earlier analyses, arising from continuing update of nomenclature and results of field surveys. The information contained in each original report may not necessarily reflect present knowledge or taxonomic usage. One species for adding to the list of species that could be eradicated from Australia (because it is likely to have a significant impact on natural ecosystems and it does not seem to be completely out of control at present) is *Passiflora tarminiana* (listed in the Appendices as *P. mollissima* commonly known as Banana passionfruit). This species is an important environmental weed in New Zealand and has been observed recently becoming so at sites in Victoria and New South Wales. The taxon *Koelreuteria elegans* ssp. *elegans* is listed in Table 4 as a possible species for containment or eradication. This species, now also naturalised in New South Wales, should more correctly be referred to as *K. formosana* (or *K. elegans* ssp. *formosana*). It is a popular ornamental plant and the species is likely to be more widely naturalised than current herbarium records suggest. Based on the process referred to in Appendix 1 and addressed in Appendix 3, the Department of the Environment and Heritage has established a national environmental alert list. The list currently contains 28 species, and detailed information covering their description and management is being prepared for distribution. The information presented in this book has also been used to inform Department of Agriculture, Fisheries and Forestry projects on agricultural sleeper weeds.

## APPENDIX 1

TERMS OF REFERENCE FROM THE  
DEPARTMENT OF THE ENVIRONMENT  
AND HERITAGE

The Invasive Species Section of the Australian Government Department of the Environment and Heritage contracted the Cooperative Research Centre (CRC) for Australian Weed Management Systems to:

1. Organise a peer-group review by weed experts from all States and Territories to consider current knowledge about naturalised non-native plants and to group them into broad-band categories based on:
  - a. their impact on native species, in particular nationally-listed endangered or vulnerable species;
  - b. their effect on ecosystem function;
  - c. their current and potential distribution; and
  - d. their invasive ability and rate of spread.
2. Identify those naturalised non-native plants that are in the early stages of establishment and range expansion and for which early intervention could lead to their containment or eradication.
3. Prepare a summary report of the recommended categories for naturalised non-native plants and list priorities for those species considered of greatest threat but still amenable to early intervention.

These Terms of Reference were met in the form of a progress report to the Department of the Environment and Heritage submitted by the CRC for Australian Weed Management on May 15, 2000 and a final report on June 30, 2000.

## APPENDIX 2

### TERMS OF REFERENCE FROM THE BUREAU OF RURAL SCIENCES

APPENDIX

2

Terms of  
Reference  
BRS

The Bureau of Rural Sciences, within the Australian Government Department of Agriculture, Fisheries & Forestry, contracted the Cooperative Research Centre (CRC) for Australian Weed Management to:

1. Organise a peer-group review by weed experts from all States and Territories to consider current knowledge about the 2681 naturalised non-native plant species in Australia and sort them into broad-band categories (categorised as major, minor or no risk) based on:
  - a. their impact or potential impact on profitability and sustainability of primary industries and the natural resource base;
  - b. their current and potential distribution;
  - c. their invasive ability and rate of spread.
2. For naturalised plants categorised as high risk, identify the primary industries most at risk from further spread.
3. For naturalised plants categorised as high risk, identify those that are limited to one or a few populations in the early stages of establishment and range expansion and for which early intervention could lead to their containment or eradication.
4. Prepare a summary report of the recommended categories for naturalised non-native plant species and list priorities for those species considered of greatest threat to primary industries and the natural resource base but still amenable to early intervention.

These Terms of Reference were met in the form of a progress report to the Bureau of Rural Sciences submitted by the CRC for Australian Weed Management on March 15, 2001 and a final report on October 31, 2001.

## APPENDIX 3

A national listing of the naturalised non-native flora of Australia arranged alphabetically by genus then species. National categories of these 2681 species in the Australian flora are listed according to their impact, weed status, ability to be controlled and their potential for further spread in natural ecosystems.

Genus	Species	Subspecies or variety	Alternate names and notes	Family	Australian rating	Potential to spread	Considered to be native by some state herbaria	Impact on ANZECC Rare & Threatened Plant Species	Habitat specific	Primarily agricultural or ruderal weed	Controlled or Noxious	Potential to control

## APPENDIX 4

A national listing of the naturalised non-native flora of Australia arranged alphabetically by genus then species.  
National categories of these 2732 species in the Australian flora are listed according to their impact, weed status, ability to be controlled and their potential for further spread in agricultural ecosystems.

Genus	Species	Subspecies or variety	Alternate names and notes	Family	Australian rating	Old rating	NSW rating	Vic rating	Tas rating	SA rating	WA rating	NT rating	Harbour for Disease (D) or Insect Pests (I) or Toxic (T)
<i>Abelia</i>	x <i>grandiflora</i>		hybrid between <i>Abelia chinensis</i> and <i>Abelia uniflora</i>	<i>Caprifoliaceae</i>	+	+	+	+	+	+	+	+

Weeds currently cost Australia billions of dollars each year in lost agricultural production. They also cause untold damage to Australian native species and ecosystems. Many introduced plants are waiting in the wings with the potential to become future weeds. This book brings together the current knowledge on the 2700 non-native plants that have naturalised in Australia. Each species is assessed for its impact or potential impact as a weed of natural and agricultural ecosystems.

The authors recommend some species as targets for eradication programs. Eradication at relatively low cost is feasible for some species if action is taken before they become invasive and spread widely. Such action could save Australia from huge future losses.

The authors are drawn from all of the States and Territories of Australia and are scientific experts on weeds and the Australian flora. The information they present here will be invaluable for weed managers, other decision makers and researchers concerned with natural resource management at a local, regional or national level.
