SUMMARY

This report details the second set of results of a project designed to contribute to the development of an inventory of Threatened Ecological Communities in Western Australia. The project builds on earlier work developing a digital vegetation map database for the State and assessing the levels of representation of each vegetation type in the conservation reserve system. This project focuses on that part of the South West Agricultural Region that is commonly known as the wheatbelt, where the native vegetation has been extensively cleared for agriculture and where, as a consequence of the clearing, there are problems of rising groundwater and the related problem of salinisation. The study area is the 12 major Soil Landscape Zones within the South West Agricultural Region where salinity is considered to be a major problem.

Vegetation associations occurring within the South West Agricultural Region were subdivided into units within each of the 12 Soil Landscape Zones. We refer to these more finely discriminated units as sub-associations. The intersection produced 459 vegetation sub-associations. These sub-associations were then analysed in conjunction with data sets of native vegetation extent, the conservation estate and soils with evidence of salinisation to identify vegetation units that are poorly represented in the present conservation reserve system, restricted in present extent and at risk from rising groundwater.

Data on the 459 vegetation sub-associations are provided. Of these, 181 have less than 10% of their original areal distribution remaining, and a further 174 have <30% remaining. Three hundred and two vegetation sub-associations have <2,000 ha remaining in the South West Agricultural Region. One hundred and seventy-two vegetation sub-associations are completely unrepresented in the conservation estate. These sub-associations are not represented in conservation reserves that fit criteria for IUCN Reserve Categories I-IV, or on other categories of CALM-managed land. An additional 29 sub-association are unrepresented in reserves that fall into IUCN Reserve Categories I-IV but are represented to a small degree on other CALM-managed lands. A further 194 vegetation sub-associations have <15% of their original areal extent in reserves that fall into IUCN Reserve Categories I-IV. A total of 77 sub-associations are potentially at risk from rising groundwaters and associated salinisation: 17 sub-associations have 100% of their present extent on soils at risk from salinity, a further 40 sub-associations have >70% of their present extent on soils at risk, and an additional 20 sub-associations have >50% of their present extent on soils at risk.

The project identifies 13 vegetation sub-associations that should be given priority for further research, because they are extensively cleared or have limited extent, are associated with saline soils so potentially at risk, and completely unrepresented in the present conservation reserve system. They should be considered for classifying as Threatened Ecological Communities.

INTRODUCTION

In Western Australia, the process of identifying biodiversity entities at the ecosystem scale began in 1994, with a project entitled *Identifying and conserving threatened ecological communities (TECs) in the South West Botanical Province* (English and Blyth 1997, 1999). A major limitation that was encountered during the project was the lack of data of sufficient quality to assess many of the communities possibly threatened against the criteria for defining categories of conservation status. This limitation was particularly acute in the part of the South West Botanical Province commonly known as the wheatbelt. In this region, it is known that there are many special biological values, yet the biota is poorly documented overall. At the same time, there are seriously threatening processes in force, including land clearing and fragmentation, and rising groundwater and associated salinisation which are a direct consequence of the clearing of the deep-rooted native vegetation (eg Government of Western Australia 1996). There is an imperative, therefore, to improve substantially the protection and management of the remaining biological values. One means to achieve this is through the threatened ecological communities process.

The recent development of a comprehensive, digital vegetation map database for Western Australia (Hopkins *et al.* 1996) provided an opportunity to address the gaps in knowledge in the wheatbelt and to contribute to the process of identifying threatened ecological communities. This data set is based on the 1:250,000 scale association-level mapping by J.S. Beard for all of the State except the south west corner which was mapped by A.J.M. Hopkins in 1998/99. Mapped vegetation units are a useful surrogate for ecosystems (Hopkins and Morgan 1999).

This project was designed to use the vegetation map database and other relevant digital data in a Geographic Information System (GIS) environment to identify some entities (ecosystems or ecological communities, see Hopkins 2000) that could be surveyed and then considered for listing as threatened ecological communities. These entities are vegetation units that are poorly represented in the present conservation reserve system and at risk.

The study was undertaken in two parts. For the first part which is reported elsewhere, vegetation associations as originally mapped at the 1:250,000 scale were used as the basic environmental unit. For this part of the study, these associations were subdivided into units within each of the 12 Soil Landscape Zones. We refer to these more finely discriminated units as sub-associations.

The objectives of this project entitled *Poorly conserved and potentially threatened vegetation types in the Western Australian wheatbelt* are:

- to identify vegetation types which are currently not represented or poorly represented in the conservation reserve system in the Agricultural Region;
- to identify those at greatest risk from rising water tables; and
- to identify remnant examples for on-ground inspection and possible acquisition, covenanting etc.

Four major outputs were envisaged:

- a list of the vegetation types of the South West Agricultural Region, derived from the 1:250,000 vegetation map database, and more finely discriminated where possible using Vegetation System boundaries and soil landform data;

- an assessment of the present reservation status of each vegetation type, derived by intersecting the vegetation map data with the cadastral data for the CALM estate;
- an assessment of potential threat to each vegetation type posed by rising water tables and salinisation, determined by intersecting the vegetation map with the digital elevation model (DEM) for the Region; and
- maps showing the patches of remnant vegetation within the distribution of each of those vegetation types which is under-represented in the CALM estate.

METHODS

The study area

This project focuses on that part of the South West Agricultural Region that is commonly known as the wheatbelt. In this part of the Region, the native vegetation has been extensively cleared for agriculture and, as a consequence of the clearing, there are problems of rising groundwater and the related problem of salinisation. The study area is the 12 major Soil Landscape Zones within the South West Agricultural Region where dryland salinity is considered to be a major problem. It excludes coastal zones which have maritime saline influences (Figure 1).

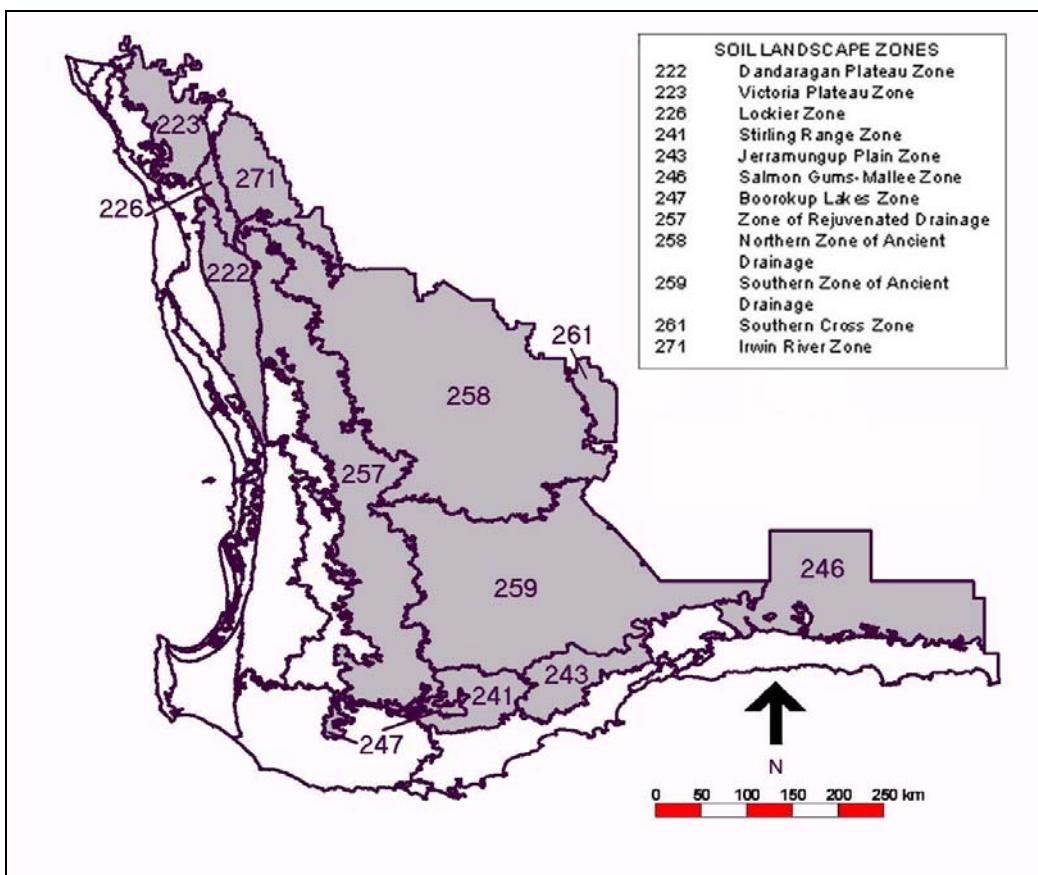

Figure 1. Map of the study area (shaded) within the South West Agricultural Region as defined by Soil Landscape Zones, showing the 12 Zones used to sub-divide the Vegetation Associations.

The data sets

Vegetation type and pre-European extent

The vegetation map database for Western Australia developed over the past 14 years is described in Hopkins *et al.* (1996), Hopkins *et al.* (in press), and Beard *et al.* (in press). In summary, the data set is based on the 1:250,000 scale mapping by J.S. Beard for the State, except the south west corner which was mapped by A.J.M. Hopkins in 1998/99. The primary vegetation units are vegetation associations *sensu* Beard and Webb (1974), but are equivalent to the sub-associations of the National Vegetation Information System (ERIN 1999). The individual polygons of each vegetation association have been captured digitally and attributed with data characterising the vegetation. It is being worked into a seamless coverage for the State. This data set is considered to best reflect pre-European vegetation patterns.

Vegetation sub-associations

The vegetation association data were intersected with the linework defining the 12 Soil Landscape Zones to produce units that we refer to here as sub-associations. The polygons of these sub-associations were then attributed with the details of Zone in addition to the association-level description. For example, the vegetation association e_{5,6}Mi Medium woodland; York gum (*E. loxophleba*) & wandoo (*E. wandoo*) (Vegetation Association Code No 7) fell into three Zones: the Zone of Rejuvenated Drainage (ZRD), the Northern Zone of Ancient Drainage and the Southern Zone of Ancient Drainage. The intersection gave rise to three sub-associations: e_{5,6}Mi/ZRD, e_{5,6}Mi/NZAD and e_{5,6}Mi/SZAD.

Present vegetation extent

Since European settlement, much of the original vegetation of the south west of Western Australia has been cleared for agriculture, resulting in a loss of biodiversity. Within the South West Agricultural Region, most of the native vegetation now exists only as isolated remnants, many of which occur on privately-owned land. A spatial database of present vegetation extent in the Intensive Land-Use Zone (South West Agricultural Region) is currently being developed for National Land and Water Resources Audit project DAW27 (Land-use and vegetation mapping: Western Australia). The data set builds on the work done for the Australian Land Cover Change Project (Barson *et al.* 2000) using the recent aerial photo coverage converted to digital orthophoto coverage (Beeston, Hopkins and Shepherd in preparation). The polygons of remnant vegetation are attributed with vegetation type data derived from the pre-European vegetation map coverage described above.

The area of present extent of each vegetation association for the whole of Western Australia was calculated as the pre European extent in the whole of Western Australia minus pre-European extent in the South West Agricultural Region plus the present extent in South West Agricultural Region.

Soil landscapes

Over south-western Australia, draft soil landscape mapping at the systems level is available (N Schoknecht, Agriculture WA personal communication, June 2000). These soil landscape systems have been proportionally attributed with WA Soil Groups (Schoknecht 1999). From this it was possible to identify those systems in which saline soils (Salt Lake Soils and Saline Wet Soils) are apparently present. For the current purpose, each system was assigned to one of four classes according to the percentage of these saline soils attributed (0%, 0-10%, 10-30% and >30%). Only soil

landscapes with saline components of 10 - 30% and >30% have been used in the analysis for this project..

The soil landscapes have been grouped into Soil Landscape Zones (Figure 1): these have been used to define the study area, and to generate the sub-associations (see above). Details of the 12 Soil Landscape Zones are included as Appendix I.

Conservation estate

The Department of Conservation and Land Management holds an up-to-date set of cadastral data for all lands and waters managed by the Department in a dedicated database – TENIS, CALM’s Tenure Information System (Bowen 1995). A comprehensive database sits behind the cadasta – this contains information on vesting, purpose and classification, and allows each parcel of land to be assigned to an IUCN reserve category (see IUCN 1994). This database was used for the conservation assessments reported here.

Analyses

The vegetation type and extent, soils and CALM-managed lands data are held as vector data, feature coded and attributed in an ORACLE database linked to Integraph’s Modular GIS Environment (MGE). The sub-association data set generated through this project was also in this form.

In order to perform analyses, it is necessary to create a topology. This topological file contains the mathematical representations of the spatial relationships that exist between graphical features; it also contains the original pointer to the data linkages from the graphical features to the relational database.

Topology files of the four discrete, spatially co-registered area-themes, pre-European vegetation sub-associations, present vegetation extent, saline soils and cadastral boundaries of the CALM-managed estate, were built and those four themes were overlaid and intersected in pairs, using the Modular GIS Analysis (MGA) module of MGE to produce a further topological file describing the results of the intersection for example, the faces of vegetation units within the CALM-managed estate. The new topologies and the linked tables were used to generate a series of reports. The data from these reports were taken into a spreadsheet program for further sorting and minor computation. The maps presented in this report were prepared using Integraph’s Geomedia software. This software was used to display the results of the analyses carried out in MGE, generate thematic maps and produce the mapping products included in this report.

RESULTS

The 236 vegetation associations reported in Part I of this project were subdivided into 459 vegetation sub-associations. These are listed in Table 1 ordered by the Vegetation Association Code No., as codes and as a full description. Further description of the soil zones is given in Appendix 1. Included in the list are a number of sparsely-vegetated units such as bare ground and granite rock that are considered to support unique vegetation but in relatively limited amounts. The sparsely-vegetated units are referred to as vegetation sub-associations for ease of discussion. It also includes some vegetation associations that are extensive outside the Agricultural Zone and only have a small area in the study area.

Also shown in Table 1 are the results of the intersection of pre-European vegetation type and extent with the present vegetation extent. One hundred and eighty-one vegetation sub-associations have <10% of their original extent remaining. Of these 28 have no remaining vegetation in these soil zones. An additional 174 vegetation sub-associations have $\geq 10\%$ but $<30\%$ of their original extent remaining. Three hundred and two vegetation sub-associations have less than 2,000 ha remaining in the South West Agricultural Region. These vegetation associations may occur outside the study area but in different soil zones or outside the agricultural clearing line. Many of these sub-associations are greatly reduced in extent. These vegetation sub-associations are coded with the letter a (<10%), b ($\geq 10\%$ but $<30\%$) and/or c (<2000 ha) in the right column of the Table. There were no vegetation sub-association which could be coded with the letter d. Code d signifying a unit with a present extent of $> 50,000$ ha.

Table 1. Pre-European and present extent of Vegetation Sub-associations in the South West Agricultural Region. Codes are a = vegetation sub-association with <10% of their original areal extent remaining, b = vegetation sub-association with <30% of their original areal extent remaining, c = vegetation association with <2,000 ha remaining in the Agricultural area.

*codes are a = vegetation sub-association with <10% of their original areal extent remaining, b = vegetation sub-association with <30% of their original areal extent remaining, c = vegetation association with <2,000 ha remaining in the Agricultural area.

Table 2 shows the results of conservation assessment. One hundred and seventy two vegetation sub-associations are completely unrepresented in the conservation estate, which includes reserves that accord with IUCN Reserve Categories I - IV ie National Parks, Nature Reserves, Marine Parks, Marine Nature Reserves, Conservation Parks, and other categories of land managed for conservation by the Department of Conservation and Land Management (CALM). Twenty nine more associations have a minor representation on other lands managed by CALM. An additional 194 vegetation sub-associations have <15% of their original, pre-European extent in reserves that fall into IUCN Reserve Categories I – IV. The total number of sub-associations (out of 460 analysed) that are poorly conserved is 396. Vegetation sub-associations that are inadequately reserved are identified with the letters e (no representation), f (0 representation in reserves in IUCN categories I-IV and <15% in other CALM-managed lands) or g (<15% in reserves in IUCN categories I-IV).

Table 2. Reservation status of vegetation sub-associations in the South West Agricultural Region of Western Australia (as at March 2000)
 Codes are e = vegetation sub-association completely unrepresented in reserves in IUCN categories I-IV or in other CALM managed land, f = vegetation sub-association unrepresented in reserves in IUCN categories I-IV reserves but with < 15% of their original extent in other CALM managed lands, g = vegetation sub-association inadequately represented in the conservation reserve system with <15% of their original extent in reserves in IUCN categories I-IV.

*codes are e = vegetation sub-associations completely unrepresented in IUCN I- IV reserves or other CALM-managed lands, f = vegetation association unrepresented in IUCN I- IV reserves but <15% of their original areal extent in other CALM-managed lands, g = inadequately represented in the conservation reserve system with <15% of their original areal extent in IUCN I- IV.

Table 3 shows those vegetation sub-associations that may be regarded as at risk from rising ground waters and associated salinisation. Seventeen vegetation sub-associations have 100% of their present extent in areas of soils at risk from salinity. A further 40 sub-associations have >70% of their present extent in areas of soils at risk from salinity. Twenty sub-associations have >50% of their present extent in areas of soils at risk from salinity. The total number of vegetation types at risk (out of the 464 analysed) is 78. These vegetation sub-associations at risk are coded h (100% at risk), I (>70% at risk) or j (>50% at risk).

Table 3. Vegetation sub-associations potentially at risk from rising ground water and salinisation. Codes are h = vegetation sub-association with 100% of its remaining extent at risk, i = vegetation sub-association with >70% of its remaining extent at risk and j = vegetation sub-association with > 50% of its remaining extent at risk.

*codes are h = vegetation sub-association with 100% of its remaining extent at risk, i = vegetation association with >70% or its remaining extent at risk, j = vegetation association with >50% or its remaining extent at risk.

Table 4 represents a distillation of the data in Tables 1, 2, 3. The table shows those vegetation sub-associations that show all of the following characteristics:

- extensively cleared with less than 10% of their original areal extent remaining, or relatively restricted in distribution occurring over less than 2,000 ha, or both;
- completely unrepresented in the conservation reserve system or on other lands managed by CALM, and therefore a priority for acquisition;
- greatly at risk from rising groundwater and salinisation.

A total of 13 vegetation sub-associations are identified. These vegetation sub-associations should be given high priority for field survey leading to improved conservation and management. Figures 2-14 show the general location and distribution of these priority sub-associations.

Table 4. Summary of analyses showing the vegetation sub-associations that are relatively restricted in areal extent, poorly conserved and at risk

CONCLUSIONS

This report gives the results of the assessment of conservation status and threat of sub association-level vegetation units in the Western Australian wheatbelt. Data on some 459 vegetation sub associations are provided. Almost all (395 of the 459) are under-represented in the conservation reserve system: 172 are not represented at all. And 77 sub associations are potentially at risk from rising groundwater and associated salinisation.

Thirteen vegetation sub associations have a combination of high priority or risk characteristics for all three attributes studied here: they are extensively cleared, associated with saline soils so potentially at risk, and poorly represented in the present conservation reserve system. These 13 sub associations should be given highest priority for further research. Since the project is a desk-top one, such research should begin with on-ground survey.

The data are amenable to reanalysis to identify other priority vegetation sub associations eg those that are at less risk. Tables are available in digital form on request.

The 13 high priority vegetation sub associations listed in Table 4 should be evaluated against criteria for Threatened Ecological Communities (Blyth and English 1999). Other, lower-priority sub associations could be considered for entry in the TECs database in a lower risk category.

ACKNOWLEDGEMENTS

We thank Damian Shepherd Sefano Mazzilli, Gerg Beeston and Ruth Morgan for their invaluable contribution to this project.

Appendix 1. Description of Soil Landscape Zones used to define Vegetation Sub-associations and for the analysed in this project.

ZONE No.	ZONE Code	ZONE	ZONE DESCRIPTION
222	DPZ	Dandaragan Plateau Zone	Gently undulating plateau with areas of sandplain and some laterite. On Cretaceous sediments. Broad U-shaped valleys 80-150m deep, smaller V-shaped east of Gingin scarp in the south. Soils are formed in colluvium and weathered rock.
223	VPZ	Victoria Plateau Zone	Gently undulating sandplain on Silurian sandstone and Proterozoic granulite with laterite exposed at dissected margins.
226	LZ	Lockier Zone	River valleys of the Irwin, Lockier and Arrowsmith rivers. Alluvial valley plains underlain by Proterozoic granulites, Permian and Jurassic sediments. Outliers of Victoria Plateau Zone occur within the zone. Clayey to silty soils.
241	SRZ	Stirling Range Zone	Steep mountains of the Stirling Ranges (Proterozoic metasediments) and undulating rises on Archaean granitic rocks in the Upper Pallinup catchment.
243	JPZ	Jerramungup Plain Zone	Level to gently undulating plain dissected by a number of short rivers flowing south. On Eocene marine sediments overlying Proterozoic granitic and metamorphic rocks. Soils are alkaline sandy duplex soils with some clays, sands and gravels.
246	SGMZ	Salmon Gums-Mallee Zone	Level to gently undulating plain, with Tertiary sediments over Proterozoic granites. Salt lakes, scattered or in swarms are a common feature. Drainage lines become indistinct towards the north.
247	BLZ	Boorokup Lakes Zone	Poorly drained flats with lake systems on Eocene sedimentary deposits. Sandy duplex soils.
257	ZRD	Zone of Rejuvenated Drainage	Erosional surface of gently undulating rises to low hills. Continuous stream channels that flow in most years. Colluvial processes are active. Soils formed in colluvium or in-situ weathered rock.
258	NZAD	Northern Zone of Ancient Drainage	An ancient peneplain with low relief. There is no connected drainage, salt lake chains occur as remnants of ancient drainage systems which now only function in very wet years. Lateritic uplands dominated by yellow sandplain.
259	SZAD	Southern Zone of Ancient Drainage	An ancient peneplain with low relief. There is no connected drainage, salt lake chains occur as remnants of ancient drainage systems which now only function in very wet years. Lateritic uplands dominated by grey sandy gravel plain.

Appendix 1. Description of Soil Landscape Zones used to define Vegetation Sub-associations and for the analysed in this project.

261	SCZ	Southern Cross Zone	Rises and low hills on Archaean greenstones, with broad valleys often containing salt lake chains. Soils are usually red, loamy to clayey and calcareous.
271	IRZ	Irwin River Zone	The Irwin and Lockier River catchments within the Yilgarn Craton. Archaean granites, gneisses, metasediments and basic igneous rocks.
