

Nomination (to be completed by nominator)

Current conservation status								
Name of ecological community:		Herb rich shrublands in clay pans (floristic community type 8 as originally described in Gibson <i>et al.</i> (1994)						
Other names:	Swan Coastal Plain	community 8 (SCP)	08).	Floristic community ty	/pe 8 (FCT08).			
Description:	The community has been recorded between Bullsbrook and Ludlow, and occurs in low lying flats with a clay impeding layer that facilitates seasonal inundation. The vegetation can be dominated by <i>Viminaria juncea</i> (swishbush), <i>Melaleuca viminea</i> (mohan), <i>Melaleuca lateritia</i> (robin redbreast bush) or <i>Melaleuca osullivanii</i> (broombush) but also occasionally by <i>Eucalyptus wandoo</i> (wandoo). The occurrence of species such as <i>Hypocalymma angustifolium</i> (white myrtle), <i>Acacia lasiocarpa</i> var. <i>bracteolata</i> (long peduncle form) and <i>Verticordia huegelii</i> (variegated feather flower) at moderate frequencies, and aquatic annuals is common. The community is also known as "floristic community type 8" as originally described in Gibson N., Keighery B.J., Keighery G.J., Burbidge A.H. and Lyons M.N. (1994) "A floristic survey of the southern Swan Coastal Plain" (unpublished report for the Australian Heritage Commission prepared by the Department of Conservation and Land Management and the Conservation Council of Western Australia (Inc.)).

		VU under A3 is the most robust and conservative rank as vegetation clearing data are regional and not sufficiently corroborated in relation to this community to support a higher rank.					
В.	Restricted geographic distribution (EOO and AOO, number of locations and evidence of decline)	B1 (specify at least one of the following): a)(i) □a)(ii) ⊠a)(iii) ⊠b) □c); B2 (specify at least one of the following): a)(i) □a)(ii) ⊠a)(iii) ⊠b) □c); B3 (only for Vulnerable Listing)					
	Justification of assessment under Criterion B.	 B1: EOO is 2991km². Community meets the threshold for Endangered as it occupies ≤20,000km² (threshold for EN is ≤20,000km² and for CR is ≤2,000km²). B1aiii) Community is subject to measurable decline from observed and inferred ongoing weed invasion (ie. biotic interactions, see criterion D, and Appendix 1 below). B1b) Continuing decline observed and inferred from the historic and ongoing impacts of land clearing, hydrological change (alterations to surface water), weed invasion, altered fire regimes, grazing by introduced fauna, and a drying and warming climate that are likely to cause continuing decline in geographic distribution and environmental quality within the next 20 years (see Appendix 1 for details of threats). B2: AOO is 1400km² (occupies 14 10x10 km² grid cells). Community meets threshold for endangered with ≤20 cells occupied (threshold for CR is ≤2 grid cells). B2aiii) Community subject to measurable decline from observed and inferred ongoing weed invasion (as for B1aiii). B2b): As for B1b, continuing decline observed and inferred from the historic and ongoing impacts of threats likely to cause continuing decline in geographic distribution and environmental quality within the next 20 years. B1c: Community is considered to occur at 15 threat-defined locations based on clusters of bushland areas subject to similar management, and threats. Community exists at more than 10 threat-defined locations. Does 					
		not meet B1c, B2c or B3. • Meets criteria for Endangered B1a(iii),b; B2a(iii),b					
C.	Environmental degradation of abiotic variable (Evidence of decline over 50-year period)	☐ C1 ☐ C2 ☐ C3					
	Justification of assessment under Criterion C.	 Altered hydrology is a significant abiotic variable affecting the community. Alterations to depths or seasonality of surface water will result in subsequent changes to composition, in particular to the defining herbaceous layer in the community. 					
		For criterion C, it is assumed the community will collapse when seasonal inundation with surface water no longer occurs. It is assumed that such severe changes to surface water will results in loss of the defining herbaceous wetland adapted flora in the					

		community. Reductions and other changes to seasonal inundation patterns are directly related to rainfall (See Appendix 1 for further details).				
		 There are inadequate quantitative data to link changes to surface water regimes (depths and seasonality) to compositional changes in the community. It is therefore not possible to determine the severity of current or projected declines in rainfall and surface water in relation to the collapse point (also see Appendix 1 for details of threats). 				
		 There are inadequate data to determine if community meets minimum thresholds for proportion of the extent (≥30%) or proportional severity of degradation (≥30%) over any 50 year period, or (≥50%) or proportional severity of disruption of abiotic processes (≥50%) since 1750 to meet the criteria for VU. 				
		 Insufficient evidence to determine if the community meets criterion C 				
D.	Disruption of biotic processes or interactions (Evidence of decline over 50-year period)	□ D1⋈ D2□ D3				
	Justification of assessment under	Weed invasion is a significant biotic threat to the community.				
	Criterion D.	 The severity of weed invasion associated with collapse is uncertain, but it is assumed conservatively that the community reaches a collapsed state when only 10% (plausible range 0–20%) of its plant species are native. 				
		 Weed data taken from 17 quadrats across 5 occurrences (FL03, BRIX01, BRIX04, MUD02, MUD09, ELLEN01, MEELON01, PM14 and PM28) (representative of 38% of the extent of the community) indicate an increase in the average proportion of exotic species between 1994 to 2017-2018 with an 8% reduction of native taxa. 				
		• It is assumed that the increase in introduced taxa as indicated by 17 quadrats is linear and is representative of weed invasion across the occurrences in which the specific quadrats occur. Based on these assumptions, 38% of the extent of the community has a projected 18% decline in native taxa in the next 50 years. This represents a projected reduction to the proportion of native species to 52% (ie. 48% are weed taxa) across 38% of the extent of the community over the next 50 years. This corresponds to a projected 53% severity in relation to the collapse point of ≥90% weeds (ie. 48/90 x100%), within the next 50 years, in the absence of effective weed management.				
		 The community does not fall below the collapse threshold of ≤10% native taxa (ie. ≥90% weeds) within the surveyed 25-year period and is not projected to do so within the next 50 years. 				
		 According to available weed monitoring data, the community does not meet the threshold of ≥30% of the extent of the community subject to relative severity of weed invasion of ≥80% to meet VU under criterion D2a. 				
		 Available weed data indicate the community does not meet criterion D.

^{*}Vegetation condition categories from Keighery (1994) Vegetation Condition Scale in Bush Forever (Government of Western Australia 2000) are defined below:

Good ('Pristine', 'Excellent', 'Very Good' using Bush Forever (2000) scale): This includes vegetation ranging from 'Pristine' - with no obvious signs of disturbance, to 'Excellent' - Vegetation structure intact, with disturbance only affecting individual species, weeds are non-aggressive species and 'Very Good' - Vegetation structure altered, obvious signs of disturbance eg: from repeated fires, dieback, logging, grazing.

Medium ('Good' using Bush Forever (2000) scale): This includes vegetation categorised as 'Good' - Vegetation structure altered but retains basic vegetation structure or ability to regenerate it, obvious signs of disturbance are present, from activities including partial clearing, dieback and grazing.

Poor ('Degraded', 'Completely degraded' using Bush Forever (2000) scale): This includes vegetation ranging from 'Degraded' Basic vegetation structure severely impacted by disturbance, the vegetation requires intensive management, and disturbance such as partial clearing, dieback, logging and grazing, to 'Completely Degraded' where vegetation structure is no longer intact and the area is completely or almost completely without native species. These areas are often described as 'parkland cleared' with the flora comprising weed or crop species with isolated native shrubs and trees.

APPENDIX 1 THREATS

Taken from Department of Parks and Wildlife ((DPAW) 2015)

Vegetation clearing

The seasonal clay-based wetland communities of the south west are amongst the most threatened assemblages in Western Australia. It is estimated that >90% of the original extent of these wetlands has been cleared for agricultural use (Gibson *et al.* 2005). Clay pans in the Perth area have also historically been cleared and quarried for clay for use in manufacturing bricks and tiles.

Weed invasion

Weeds displace native plants, particularly following disturbances such as too frequent fire, grazing or partial clearing, and compete with them for light, nutrients and water. They can also prevent recruitment, cause changes to soil nutrients, and affect abundance of native fauna. They can also impact on other conservation values by harbouring pests and diseases, and increasing the fire risk.

Introduced South African bulbous plants are a particularly serious group of weeds in clay pans. As the taxa occur in similar habitat in South Africa, many have the ability to invade relatively undisturbed clay pan habitat and displace the rich herbaceous flora. Watsonia meriana, Sparaxis bulbifera (harlequin flower), Moraea flaccida (one leafed cape tulip), Hesperantha falcata and Freesia alba x lechtlinii (freesia) are of particular concern. Seed and cormels are spread into undisturbed areas in sheet waterflow across wetlands (Brown and Brooks 2003b; Brown et al. 2008). South African perennial grasses are another serious group of weeds that also occur in similar habitat in South Africa and have the ability to invade clay pans in good condition following disturbance events such as fire. Tribolium uniolae (haas grass), Eragrostis curvula (lovegrass) and Hyparrhenia hirta (tambookie grass) are of particular concern and are a priority for control. The impacts of annual weeds are less well known but many move into intact vegetation following a disturbance event and appear to displace the native annual flora. These include Cyperus hystrix, Parentucellia viscosa (bartsia) and Hypochaeris glabra (flat weed).

Sources of weed invasion include adjoining areas of urban and agricultural use, drains, and tracks within and near the clay pans. All these sources increase vulnerability to weed invasion following any type of disturbance. The clay pans may appear reasonably resistant to weed invasions due to seasonal inundation and hardness of soils in the summer and changes to these elements may alter their ability to resist weed invasion (Keighery 1996).

Quadrats established in 1992 in ephemeral claypans during a regional survey of the Swan Coastal Plain (Gibson *et al.* 1994), were resurveyed in 2012 (Gibson *et al.* 2018). A decrease in native species richness, from an average of 38.7 in 1992 to 32.9 per quadrat was indicated after 20 years (Gibson *et al.* 2018). Invasive taxa had increased in richness by 33% from an average of 10.8 taxa to 14.2 taxa per quadrat over the same 20-year period. Six particularly aggressive South African exotic flora had spread into an additional 37% of the previously non-invaded quadrats, with 60% of quadrats containing these taxa at the latter timepoint, an increase of 23%. The increase in exotic taxa could be expected due to the highly fragmented nature of the remnants (Gibson *et al.* 2018). The authors surmise that variability in inundation period in the last decade may be increasingly facilitating a longer period of weed establishment in some years. This indicates that declining rainfall may also be implicated in increased weed invasion in claypans.

Webb (2019) also compared data for proportion of native and weed species in occurrences of the community in 1994, and at a timepoint between 2010 and 2018. Linear projections of a 50-year forecast based on these trends are shown in Figure 1 below. Linear projections have been calculation based on these two timepoints. The projection indicates that if weeds are unmanaged in these occurrences, the proportion of native species will decline to approximately 52% of the total number of species in the community within the next 50 years (ie 48% weeds).

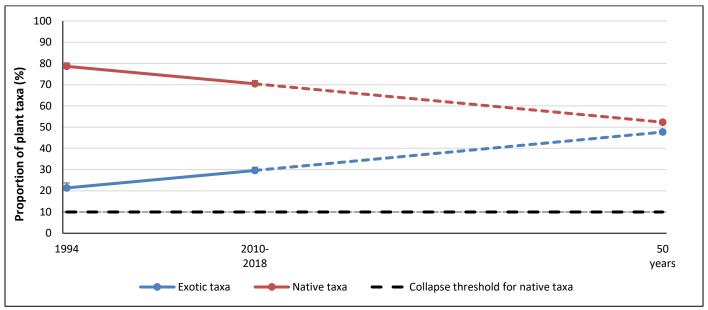

Figure 1. Trend in the proportion of native and exotic plant species based on the mean of 17 sampled sites. 16 sites are located in the Swan region and 1 located in the South-west region (n = 17). A 50-year forecast was calculated using a linear trendline of the proportion of exotic taxa (y=0.3467x+20.971) and the proportion of native taxa (y=-0.3467x+79.029) (Webb 2019).

Hydrological changes

Hydrology is the main driver of the ecological functions of clay pans. The biota associated with low lying areas, including damplands, palusplains and basins, are adapted to, and require, seasonal flooding and shallow water tables for their long-term persistence (Bourke 2017). Variations in depth and timing of inundation influence the suites of flora that occur in a particular location, resulting in variation in the community's composition across its extent (DPaW 2015). Changes in hydrological status will significantly alter the assemblages in the communities (DPaW 2015).

Hope (2015) https://www.climatechangeinaustralia.gov.au/en/publications-library/cluster-reports notes that "There has been a prolonged period of extensive drying from the 1970s in the Southern and South Western Flatlands (SSWF) and from the 1990s to the present in both sub-clusters, particularly in autumn and early winter. Decreases in winter and spring (and annual) rainfall are projected with high confidence. There is strong model agreement and good understanding of the contributing underlying physical mechanisms driving this change (relating to the southward shift of winter storm systems and greater prevalence of high pressure systems). By 2030 winter rainfall may change by -15 to +5 %. By 2090, these ranges are around -30 to -5 % under Representative Concentration Pathways (RCP) RCP4.5 for Southern and South Western Flatlands Western Cluster (SSWFW), and -45 to -15 % under RCP8.5. For Southern and South Western Flatlands Eastern Cluster SSWFE, under RCP4.5 by 2090 the changes are -25 to 0 % while under RCP8.5 the range is -45 to -5 %. For the whole cluster (SSWF), under RCP4.5 by 2090 the range is -25 to -5 % while under RCP8.5 the range is -45 to -15 %." These scenarios are indicative of trends in climatic drying that are likely to affect the depth and seasonality of inundation of the clay pan communities. This has major implications for the future of the clay pan floral assemblages.

Altered hydrology due to anthropogenic causes, in urbanised areas in particular, is likely to be an increasing threat to the clay pans. Drainage to lower watertables, clearing resulting in a decline in evapotranspiration and increased surface runoff, and water quality declines are likely to increasingly impact the hydrologic regimes of the clay pan communities. Altered periods of ponding may affect the timing of growth of herbs in the understorey, and may also affect the species composition of the community by favouring different taxa. Any changes to the natural hydrology of the clay pans can affect composition as they are dependent on the timing of filling and drying at appropriate times of the year. Bourke (2017) suggests it is likely that changes to the hydrological cycle of the occurrence of the claypan community within Greater Brixton Street Wetland area have already occurred or will occur in the future. Also, given the lack of understanding of the current and historical hydrological functioning of this area, the development of a robust conceptual hydrological model for this site is essential.

Increased nutrient levels in surface water in occurrences adjacent to areas such as farm lands and residential areas is likely to favour weeds as they are adapted to higher nutrient levels than native flora.

Fire regimes

Inappropriate fire regimes are a significant threat to the clay pan communities. Historically, fire within the clay pans was probably only very occasional. It is likely that some of the clay pan sub-types such as the Shrublands on dry clay

flats may be adapted to occasional fire as they contain species that will easily carry fire when vegetation is dry, and some component shrubs would reproduce from seed following fire. The fire response of the major types of clay pan vegetation needs to be determined however.

The risk of fire is generally increased by the presence of urban areas nearby. In addition, grassy weeds in the understorey are often more flammable than many of the original native species in the herb layer.

APPENDIX 2: Distribution of Herb rich shrublands in clay pans (floristic community type 8 as originally described in Gibson *et al.* (1994))

APPENDIX 3: Area and proportion remaining for vegetation complexes that support occurrences of Herb rich shrublands in clay pans (floristic community type 8 as originally described in Gibson et al. 1994)

Vegetation Complex	Area of vegetation complex in occurrences of SCP08 (ha)	SCP Pre- European Extent (ha) of complex	SCP % Remaining	SCP Pre-European Extent secure for Conservation (EPA definition) (ha)	SCP Current percentage remaining within lands secure for Conservation (EPA definition) (%)
Beermullah complex	5.72	6707.27	6.67	145.38	2.13
Guildford complex	121.18	90513.13	5.09	373.62	0.33
Serpentine River complex	17.43	19855.41	9.77	373.62	2.42
Southern River complex	114.74	58781.48	18.43	1137.82	1.37
Yoongarillup complex	8.63	27977.93	35.81	4539.74	14.14

APPENDIX 4: IUCN Red List Criteria for ecosystems (version 2.2) (IUCN 2017)

A. Re	duction in geographic distribution over ANY of the following time	periods:							
			CR	EN	VU				
A1	Present (over the past 50 years).		≥ 80%	≥ 50%	≥ 30%				
A2a	Future (over the next 50 years).		≥ 80%	≥ 50%	≥ 30%				
A2b	Future (over any 50 year period including the present and future).	≥ 80%	≥ 50%	≥ 30%				
А3	Historic (since 1750).		≥ 90%	≥ 70%	≥ 50%				
B. Restricted geographic distribution indicated by EITHER B1. B2 or B3:									
			CR	EN	VU				
B1	Extent of a minimum convex polygon enclosing all occurrences (E Occurrence)	Extent of	≤ 2,000 km²	≤ 20,000 km²	≤ 50,000 km²				
	AND at least one of the following (a-c):								
	(a) An observed or inferred continuing decline in EITHER:								
	i. a measure of spatial extent appropriate to the ecosystem; OR								
	ii. a measure of environmental quality appropriate to characteristic biota of the ecosystem; OR								
	iii. a measure of disruption to biotic interactions approp	oriate to the cha	aracteristic bio	ota of the eco	system.				
	(b) Observed or inferred threatening processes that are likely to cause continuing declines in geographic distribution, environmental quality or biotic interactions within the next 20 years.								
	(c) Ecosystem exists at		1 location	≤ 5 locations	≤ 10 locations				
B2	The number of 10 × 10 km grid cells occupied (Area of Occupancy)		≤ 2	≤ 20	≤ 50				
	AND at least one of a-c above (same sub-criteria as for B1).								
В3	A very small number of locations (generally fewer than 5) AND prone to the effects of human activities or stochastic events within a very short time period in an uncertain future, and thus capable of collapse or becoming Critically Endangered within a very short time period (B3 can only lead to a listing as VU).								
C. Env	vironmental degradation over ANY of the following time periods:								
	Relative severity								
		Extent (%)	≥ 80	≥ 50	≥ 30				
C1	The past 50 years based on change in an <u>abiotic</u> variable affecting a fraction of the extent of the ecosystem and with relative severity, as indicated by the following table:	≥ 80	CR	EN	VU				
		≥ 50	EN	VU					
		≥ 30	VU						
			≥ 80	≥ 50	≥ 30				
C2	The next 50 years, or any 50-year period including the present and future, based on change in an <u>abiotic</u> variable affecting a fraction of the extent of the ecosystem and with relative	≥ 80	CR	EN	VU				
		≥ 50	EN	VU					
	severity, as indicated by the following table:	≥ 30	VU						
			≥ 90	≥ 70	≥ 50				
	Since 1750 based on change in an abiotic variable affecting a	≥ 90	CR	EN	VU				
С3	fraction of the extent of the ecosystem and with relative	≥ 70	EN	VU					
	severity, as indicated by the following table:								
		≥ 50	VU						

D. Disruption of biotic processes or interactions over ANY of the following time periods:									
			Relative severity (%)						
		Extent (%)	≥ 80	≥ 50	≥ 30				
D1	The past 50 years based on change in a <u>biotic</u> variable affecting a fraction of the extent of the ecosystem and with relative severity, as indicated by the following table:	≥ 80	CR	EN	VU				
		≥ 50	EN	VU					
		≥ 30	VU						
			≥ 80	≥ 50	≥ 30				
D2	(D2a) The next 50 years, or (D2b) any 50-year period including the present and future, based on change in a <u>biotic</u> variable affecting a fraction of the extent of the ecosystem and with relative severity, as indicated by the following table: OR	≥ 80	CR	EN	VU				
		≥ 50	EN	VU					
		≥ 30	VU						
			≥ 90	≥ 70	≥ 50				
D3	Since 1750, based on a change in a biotic variable affecting a fraction of the extent of the ecosystem and with relative severity, as indicated by the following table:	≥ 90	CR	EN	VU				
		≥ 70	EN	VU					
		≥ 50	VU						
E. Quantitative analysis									
			CR	EN	VU				
that estimates the probability of ecosystem collapse to be:			≥ 50% within 50 years	≥ 20% within 50 years	≥ 10% within 100 years
