1. INTRODUCTION

The fine, deep basin sediments of Cockburn Sound and Warnbro Sound occupy about 60 % of the benthic habitat areas of these embayments and are not found elsewhere along the central coast of Western Australia (Wilson *et al.* 1978). The benthic faunal communities associated with these sediments are considered unique because the area is a zone of overlap between the tropical fauna from the north and the temperate fauna from the south (Wilson and Gillett, 1971; Wilson and Stevenson, 1977). Pollutants tend to accumulate in the fine organic-rich sediments that characterise relatively deep, sheltered basins and, as a result, these substances have the potential to affect benthic communities. A study of the benthic invertebrate fauna of the deep (> 10 m) basins of Cockburn Sound and Warnbro Sound was undertaken in collaboration with the WA Museum. The study provides a quantitative description of the species composition, abundance and biomass of the benthos of these basins, determines if the distribution of the benthos is related to sediment characteristics, contaminant concentrations and/or ecological process changes, determines if temporal changes in species composition and abundance of selected taxa in Cockburn Sound have occurred since earlier studies (Wells, 1978; Wells and Threlfall, 1980; Wilson *et al.* 1978; Marsh and Devaney, 1978), and provides baseline data for future reference.

This data report was compiled as part of the Southern Metropolitan Coastal Waters Study (SMCWS). Further information can be found in the technical report Cary *et al.* (1995).

2. METHODS

Thirty sites in Cockburn Sound and 15 sites in Warnbro Sound were distributed evenly throughout the embayments and specific locations were based on the deep basin (>10 m) sites of the contaminant surveys of sediments undertaken in 1991 (Burt and Ebell, 1994). The field programme was undertaken over a two-week period in March/April 1993 to coincide approximately with the seasonal timing of the 1978 study of Wells (1978).

A pilot study determined that four replicates would sample 70 % of the fauna at a site. This was later supported by Chalmers (1993). A 0.1m² Van Veen grab was used to collect four sediment samples at each site. Samples were sieved in the field through 1.7 mm and 1.0 mm sieves and preserved in 10 % formalin mixed with seawater. The 1.7 mm sieve was used to enable direct comparison with the 1978 data. The fauna were grouped into six Phyla; Echinodermata, Mollusca, Annelida (Class: Polychaeta), Arthropoda (Class: Crustacea) Chordata and Cnidaria. The fauna were sorted to species, counted, identified to species level where possible and weighed. All specimens, excluding the polychaetes and crustaceans were placed individually in dilute hydrochloric acid to remove calcium carbonate and left until the reaction ceased. Specimens were then rinsed in water, dried to constant weight and then weighed, except for the polychaetes and crustaceans where only representative specimens were weighed as many of the polychaetes and crustaceans were potentially new species and specimens were retained for further taxonomic studies. A representative collection of all groups has been lodged at the Western Australian Museum.

3. RESULTS

Table 2 shows the complete list of macrobenthic fauna occurring at the 45 deep basin (>10m) sites in Cockburn and Warnbro sounds. Each species has been given a code which is used instead of the species name in Tables 3, 4 and 5. The first digit of the code is the same for each Phylum. For the Phylum annelida (500-571), only 1 replicate per site was processed except for sites 2302, 4400 WS25 and WS32 where the 4 replicates were processed.

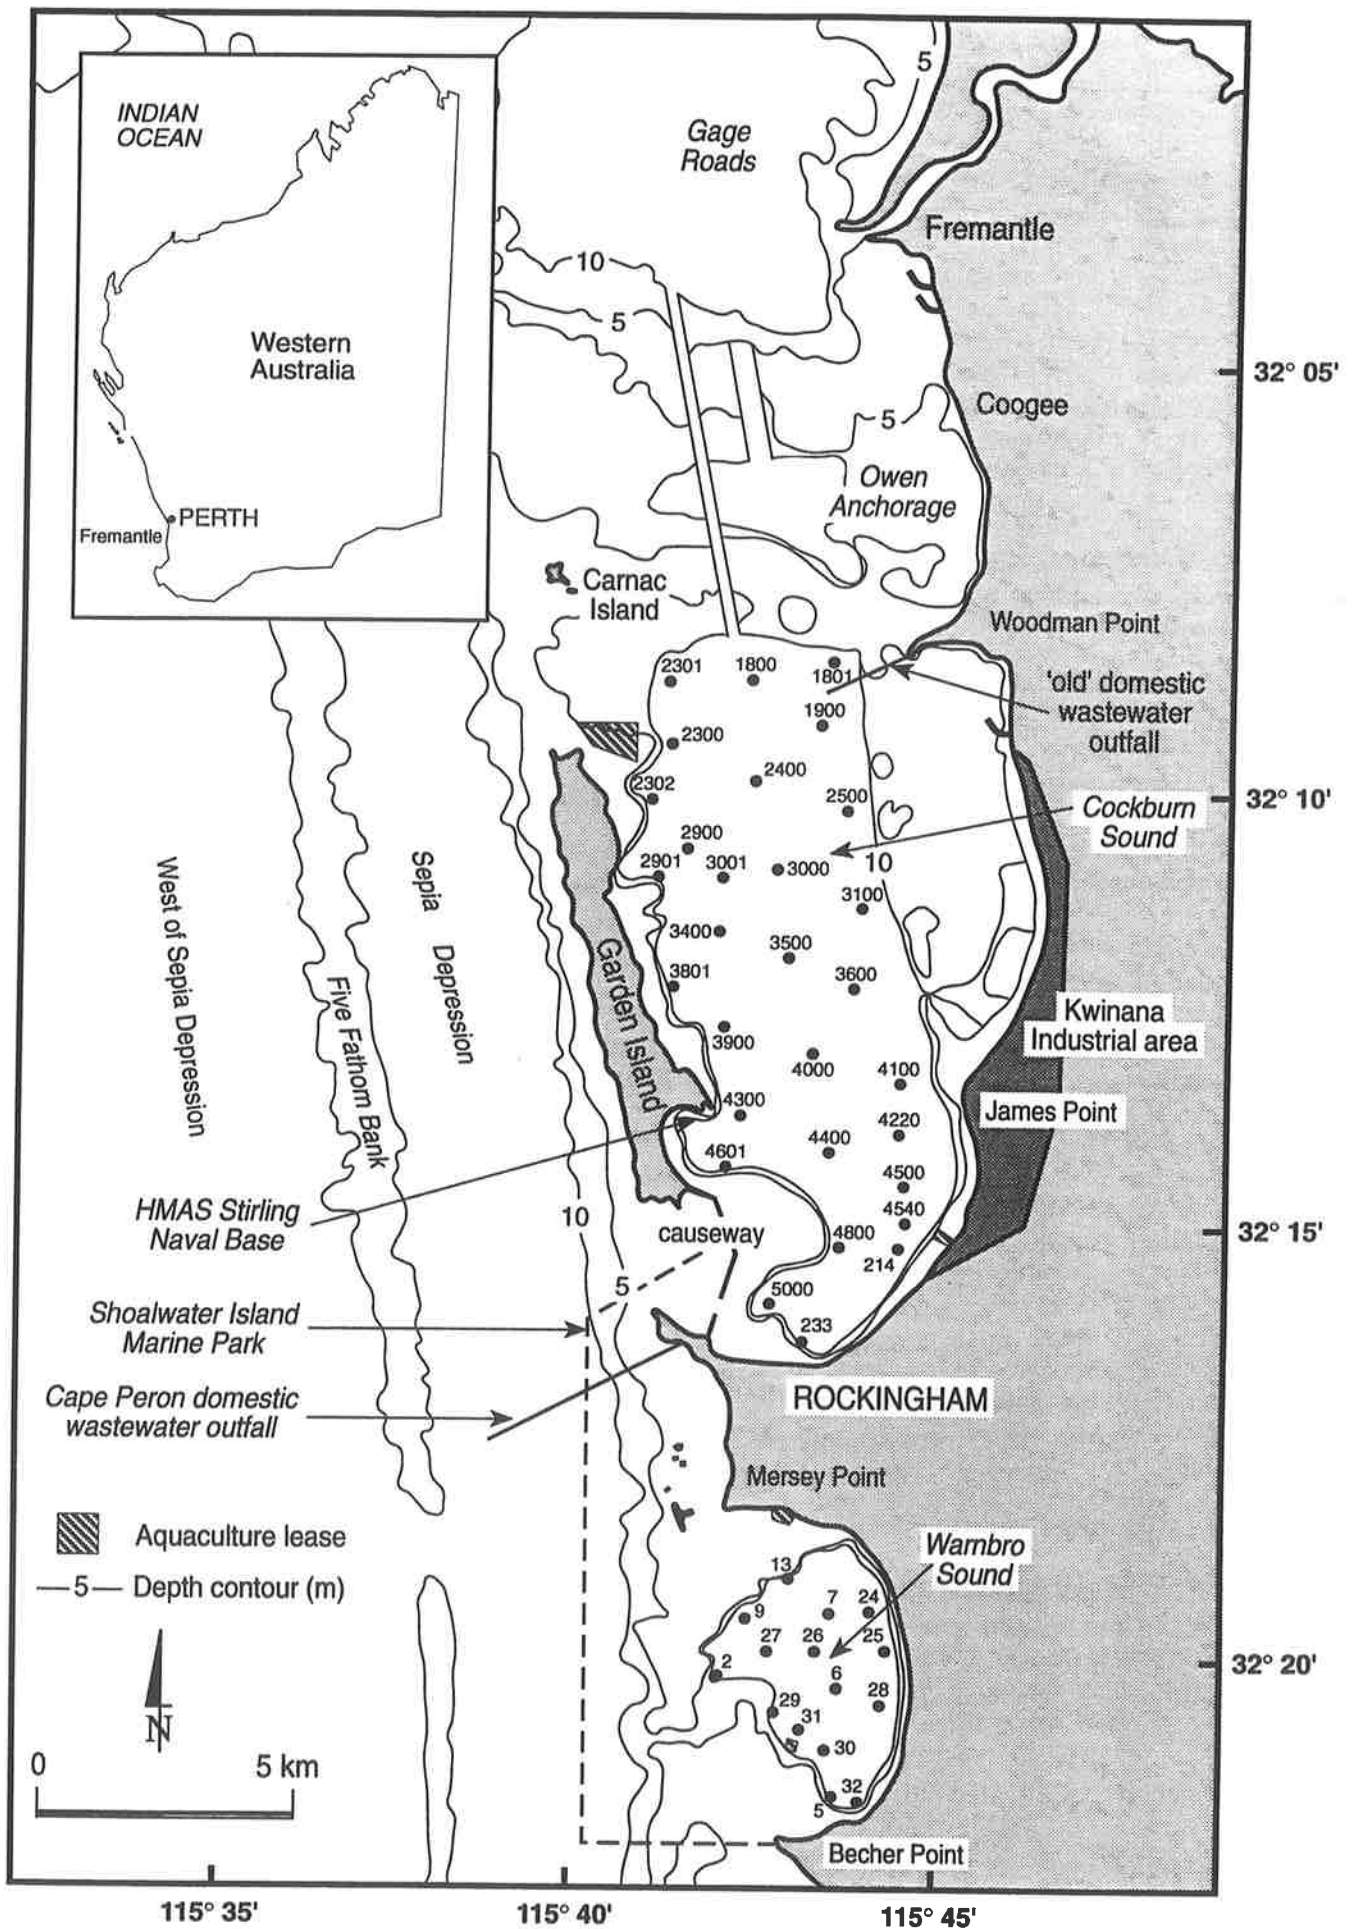

Figure 1. Location map showing sampling sites in the deep basin of Cockburn Sound and Warnbro Sound.

Table 1. Location and depth of the sampling sites in Cockburn Sound and Warnbro Sound. All coordinates have been corrected to read from charts.
