This document has been commissioned/produced as part of the Gnangara Sustainability Strategy (GSS). The GSS is a State Government initiative which aims to provide a framework for a whole of government approach to address land use and water planning issues associated with the Gnangara groundwater system. For more information go to www.gnangara.water.wa.gov.au

Acknowledgements

The Department of Environment and Conservation – Gnangara Sustainability Strategy would like to thank the following for their contribution to this publication: Dr Neil Burrows for guidance with flowering categories, Dr Leonie Valentine for her invaluable input and Leigh Sage for assistance in site selection.

Introduction

Australian plants have many adaptive vegetative and reproductive traits that enable them to persist in fire-prone environments (Gill 1981). However if intervals between fires are shorter than the time to first flowering (juvenile period) for plants killed by fire and those that are reliant on plant or soil stored seed, then too frequent fires can result in species declines (Burrows 2008). Vital attributes such as regeneration requirements, post-fire regeneration strategies, juvenile periods and the longevity of longer-lived woody species that mostly reproduce after fire are useful criteria to determine minimum and maximum intervals between lethal fires for a particular ecosystem (Burrows 2008).

As part of the Gnangara Sustainability Strategy (GSS), modifying the current burn regime by increasing the frequency of burning native vegetation on Crown land above the Gnangara groundwater system has been suggested as a cost effective technique that may increase groundwater recharge (Canci 2005; Yesertener 2007). CSIRO is undertaking an adaptive management project from 2008-2010 to examine the hypothesis that burning increases groundwater recharge. However, prior to the potential application of increased burn frequency as a management option, the biodiversity consequences of burning must be understood and the water yield and biodiversity balance quantified. DEC undertook complementary projects to assess the impacts of burning on the biodiversity of *Banksia* woodland, in particular the effect of grazing on plant juvenile periods following a prescribed burn (Mickle *et al.* 2010) and the first time to flowering across a fire chronosequence (this report).

The flowering age or ‘primary juvenile period’ (time to flowering after germination) of some common plant species found in the Gnangara Sustainability Strategy study area were assessed by Muir {, 1987 #1721}. Additionally, the Vegetation Species List and Response Database (DEC 2008) provides a valuable resource providing information on, amongst other things, flowering times, juvenile periods and post-fire regeneration strategies of plants through many parts of their distribution in the south west of Western Australia. However this information predominantly relates to plant populations occurring outside of the Swan Coastal Plain.

Results

Juvenile Period

152 plant species were observed within four replicate plots across nine fire ages (n=36; see Appendix 2). Based on a species' presence in consecutive fire ages starting from 12 months post-fire until juvenile period was attained, only 33 species provided enough information to estimate juvenile period, and only 15 of these species were present in all fire ages (Table 2). Nineteen plant species reached their juvenile period in the first 12 months following fire increasing to 30 species by 45 months post fire. 60 species were found to reach juvenile period within five years (60 months) of fire although the exact timing could not be pinpointed for all species (Table 2). Of the 60 plants attaining juvenile period within 60 months, 35% regenerated following fire by plant or soil-stored seed, and 65% by sprouting from underground structures or apical or epicormic growth.

Table 3: Juvenile period (months) of 62 plant species within *Banksia* woodland of the GSS study area and the number of fire ages in which they were present (maximum of 9). The maximum juvenile period is indicated by <45 months, for example. All juvenile periods were attained within 5 YSLF (60 months) except those indicated with #. * indicates targeted species; 'A' indicates alien species.

Only two species provided enough data to confirm their juvenile period was attained more than 5 years following fire. These include the target species *Banksia attenuata* and *Banksia menziesii* with juvenile periods of approximately 90 months (8 and 7 YSLF, respectively). Juvenile periods were able to be determined from only seven of the initial 26 targeted species including the two *Banksia* species, *Stirlingia latifolia*, *Eremaea pauciflora*, *E. beaufortioides*, *Melaleuca trichophylla* and *Petrophile linearis*. The flowering pattern of

Appendix 2. Regeneration strategies and matrix of post-fire juvenile periods and for plant species identified in fire chronosequence plots, northern Swan Coastal Plain

Number of replicates in each fire age of one to nine YSLF where juvenile periods were reached (maximum number of replicates is four). ‘0’ indicates species presence in a fire age which had not yet reached juvenile period in any replicate, while a blank cell indicates a species was not observed in that fire age. Post-fire regeneration strategy definitions are based on Burrows *et al.* (2008, see Table 2). Regeneration strategies were identified primarily from GSS study area by Mickle *et al.* (2010) and this study, supplemented by the Vegetation Response Database (DEC 2008) records (indicated by question marks, ?). * indicates the 26 targeted species and ‘A’ indicates alien species.
