SHORT COMMUNICATIONS

Acacia amputata, a new Western Australian species in section *Pulchellae* (Leguminosae: Mimosoideae)

Acacia pulchella R. Br., as defined by Maslin (1975), was excessively polymorphic, and even though A. fagonioides Benth. was subsequently removed (Maslin 1979) it remained a broadly circumscribed taxon. The status of A. pulchella was re-assessed during the preparation of an account of Acacia Mill. (Leguminosae: Mimosoideae) for "Flora of Australia". The acquisition of much new material, especially fruiting specimens, greatly aided this task. It is now seen that A. pulchella var. subsessilis differs significantly from the other varieties in its carpological features, as well as in inflorescence and vegetative characters. For these reasons it is now considered best to treat it at specific rank. The new species belongs to sect. Pulchellae (Benth.) Taub.

Acacia amputata Maslin, nom. et stat. nov.

Based on Acacia pulchella var. subsessilis Maslin, Nuytsia 1: 406, figs 4P-S & map 2 (1975). Type: Kukerin, Western Australia, 2 September 1934, C.A. Gardner s.n. (holo: PERTH 00768987; iso: CANB, K).

Conservation status. Widespread, not under threat.

Etymology. The epithet is from the Latin amputo (to cut away, lop off, shorten), in allusion to the characteristically short peduncles.

Affinities. The carpological features that clearly distinguish A. amputata from A. pulchella include the following: pods to 15 mm long and undulate to circinate; seeds transverse to oblique and mottled. In A. pulchella the pods are 1.5–5 cm long and flat or only slightly undulate; seeds longitudinal and not mottled. Inflorescence characters which generally distinguish the new species from A. pulchella include its very short peduncles and heads of 10–20 flowers. An uncommon variant of A. pulchella var. pulchella from the Busselton–Albany area (to the west of the range of A. amputata) has similar inflorescences but it is recognized by its green pinnules, longer glands (1–2 mm), slender spines, aristate bracteoles, longitudinal and non-mottled seeds, and usually longer pods (> 15 mm). Vegetatively A. amputata is similar to the inland variant of A. pulchella var. glaberrima Meisn. (fide Maslin 1975: 403) which has a similar distribution, at least for part of its range. These two taxa have numerous, prominent axillary spines and particularly small leaves, however, the new species is distinguished, in addition to the characters given above, by its hairy branchlets and acute to shortly acuminate, dark brown bracteoles. There is a suggestion that these taxa may hybridize in the Lake Grace district (e.g. K. Newbey 9485–1, PERTH).
