SHORT COMMUNICATION

The new species of *Isopogon* R.Br. described below was first collected in October 1960 on two separate occasions, firstly by Alex George from east of Newdegate and then five days later by Charles Gardner from Mt Madden. Many years previously, Gardner had drafted a treatment of the family Proteaceae for his proposed second volume of *Flora of Western Australia*, and so was well placed to recognise the distinctiveness of this new species. He called it *I. nutans* C.A.Gardner ms (on *C.A. Gardner* 13988; PERTH), but subsequently applied the name *I. cernuus* C.A.Gardner ms to the same specimen. Neither of these manuscript names was added to Western Australia's vascular plant census.

Many years later, Foreman (1995) included all specimens of the new species within one of the subspecies of *I. teretifolius* R.Br. (see Rye & Hislop 2017), but we confirmed its distinctness and gave it the phrase name *I.* sp. Newdegate (D.B. Foreman 771) in 2002 (Western Australian Herbarium 1998–). This Western Australian endemic is finally described today, some 60 years after it was first discovered.

Isopogon nutans C.A.Gardner ex Rye & Hislop, sp. nov.

Type: 7 km south of Karlgarin on Lake Grace to Karlgarin road, Western Australia, 18 September 1984, *D.B. Foreman* 771 (*holo*: PERTH 05221951; *iso*: CANB *n.v.*, MEL *n.v.*, NSW *n.v.*).

Isopogon sp. Newdegate (D.B. Foreman 771), Western Australian Herbarium, in *FloraBase*, https://florabase.dpaw.wa.gov.au/ [accessed 5 February 2018].

[Isopogon teretifolius subsp. petrophiloides (R.Br.) Foreman, Fl. Australia 16: 481 (1995), p.p., not with respect to the type.]

Shrubs to c. 1.5 m high, commonly 0.5–1 m wide, probably single-stemmed at base. Young stems smooth and reddish at first, becoming grey or brown, glabrous or early-glabrescent; hairs appressed, straight, up to 1.5 mm long. Leaves fairly erect regardless of stem orientation, simple, terete, 22–95 mm long, 1.1–2 mm wide, with a dense indumentum of long, white hairs when very young but glabrous at maturity; apex acute, with a pungent point 1–3 mm long. Flower heads axillary, pendulous, globose, 18–30 mm diam. Involucral bracts numerous, ovate or broadly ovate, 3–7 mm long, 2.7–4 mm wide,

96 Nuytsia Vol. 31 (2020)

rounded to acute; outer surface glabrous or with a few scattered hairs on the mid-line and thickened apex; inner surface glabrous. Floral bracts spathulate, (2-)3-5(-6) mm long, 1.9-2.5 mm wide; outer surface with a dense indumentum of wavy hairs 1.1–2.2 mm long in the central portion, with appressed, white and brown hairs 0.2–0.4 mm long towards the apex; inner surface glabrous. Tepals 12–16 mm long, pink; claw completely or largely glabrous; limb 2.5-3.5 mm long, deep reddish inside, the outer surface densely hairy distally or throughout, with appressed, white hairs 0.8–1.3 mm long. Anthers 1.4-2 mm long, yellow. Pollen presenter 3-3.5 mm long, yellow at first, turning orange then red, with short, finger-like papillae on the pedestal and bulge, the largest papillae c. 0.1 mm long; pedestal with continuous papillae or 4 thick rows of papillae along the 4 main longitudinal ridges; constriction well-developed; bulge 0.35-0.45 mm wide; receptor 1.2-1.5 mm long, glabrous. Cones broadly ovoid to depressed-ovoid at first, 6–17 mm wide; axis (after scales shed) ± ovoid; scales broadly obovateobtriangular, 3.3-5 mm long, 3.5-4 mm wide, with distal margin incurved, glabrous inside and on base outside, the central part with a very dense indumentum of white or ferruginous, long, wavy hairs, the top with appressed, white hairs but becoming glabrous. *Diaspores* ovoid, 2.6–3.3 mm long, 1.2–1.4 mm diam.; largest hairs widely spreading (with some directed downwards), 2.5–3 mm long; seed 1.9–2.2 mm long, 1.1–1.3 mm wide. (Figure 1)

Diagnostic features. Distinguished from other members of the genus by the following combination of characters: glabrous or early-glabrescent stems; simple, terete leaves; pendulous flower heads with glabrous or largely glabrous involucral bracts; pink tepals 12–16 mm long, with a glabrous or largely glabrous claw and a terminal tuft of hairs.

Selected specimens examined. WESTERN AUSTRALIA: Dunn Rock Nature Reserve, 30 km SW of Lake King, 15 Apr. 1984, D.J. Backshall 29 (PERTH); disused gravel pit, 23.2 km from Ravensthorpe along Floater Rd, 23 Sep. 2000, M. Bennett 597 (PERTH); Dragon Rocks Nature Reserve No. 36128, 20 Sep. 1991, A.M. Coates 2874 (PERTH); 14.8 km W of road to Ravensthorpe and Hyden at Lake King, towards Lake Grace, 24 Aug. 1992, R. Cumming 12292 (PERTH); c. 19 km S of Lake King on Newdegate—Ravensthorpe Rd, 12 Aug. 2017, R. Davis 12517 (PERTH); off South Anderson Rock Rd between Williamson and Sedgewick Rds, N of Hyden, 24 Sep. 2000, J.M. Flint 219 (PERTH); 15 km N of Ravensthorpe—Ongerup road on Koornong Rd, c. 35 km W of Ravensthorpe, 21 Sep. 1984, D.B. Foreman 805 (PERTH); Mt Madden, 19 Oct. 1960, C.A. Gardner 12878 (PERTH); Lake Camm turnoff, c. 22 miles [35 km] E of Newdegate, 14 Oct. 1960, A.S. George 1653 (PERTH); 18 km SE of Holt Rock, 17 Sep. 1976, R.J. Hnatiuk 760823 (PERTH).

Distribution and habitat. Extends from north of Hyden south-east to near Ravensthorpe, mostly within the Mallee bioregion but with the south-easternmost populations in the Esperance Plains bioregion. Grows on varied soil types including yellow sand over laterite, commonly in mallee or *Allocasuarina* shrubland.

Phenology. Flowers mainly from August to October with fruits continuing to December. There are numerous collections with mature diaspores present.

Conservation status. This species is not currently threatened as several populations occur in nature reserves.

Etymology. The epithet is Latin and means nodding or facing downwards, a reference to the pendulous inflorescences.

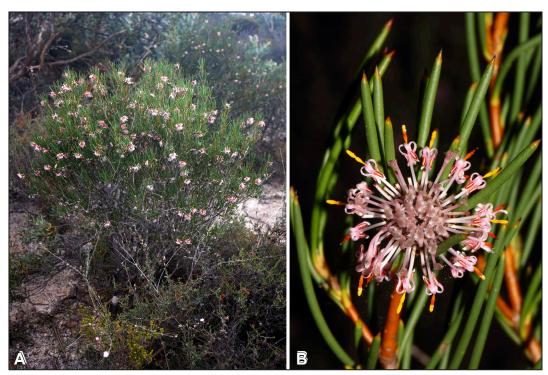

Figure 1. *Isopogon nutans*. A – habit, showing pendulous inflorescences; B – inflorescence, showing newly emerged, yellowish pollen presenters with a good coverage of yellow pollen on the receptor, and older, orange to red ones with some or all of the pollen removed. Images by Rob Davis; voucher *R. Davis* 12517.

Vernacular name. Simple-leaved Coneflower. This is one of only four species of Isopogon that have consistently simple leaves. The other species are I. autumnalis Rye & T.Macfarlane, I. robustus N.Gibson and the eastern Australian species I. fletcheri F.Muell.

Affinities. Isopogon nutans was previously included under I. teretifolius subsp. petrophiloides (R.Br.) Foreman, a simple-leaved variant of I. teretifolius that is no longer considered taxonomically distinct (Rye & Hislop 2017). Isopogon nutans differs from I. teretifolius in having glabrous or early-glabrescent branchlets and leaves (cf. with a dense, appressed indumentum on the branchlets and young leaves), involucral bracts with all or most of the surface glabrous (cf. hairs always present on the margins), apiculate floral bracts and cone scales (cf. truncate), and tepals with a glabrous claw and densely hairy limb (cf. a densely hairy claw and the limb either glabrous or with scattered hairs on its margins or apex). The typical variant of I. teretifolius is widespread and overlaps in range with I. nutans but maintains its morphological separation, the most obvious difference within the area of overlap being its divided leaves. The simple-leaved variant of I. teretifolius is geographically separated from I. nutans, occurring in the Stirling Range area.

Isopogon nutans has also been confused with I. scabriusculus Meisn., as it resembles subspp. pubiflorus Foreman and stenophyllus Foreman in having terete, simple leaves (subsp. scabriusculus has flattened, usually divided leaves) and overlaps in range with all three subspecies. All subspecies of I. scabriusculus differ from I. nutans in having short, coiled stem hairs, rougher leaves and erect inflorescences.

98 Nuytsia Vol. 31 (2020)

Identification. The key provided below distinguishes *I. nutans* from other Western Australian members of the genus with simple, usually more or less terete leaves. Note that four of the taxa keyed out below, I. adenanthoides Meisn., I. divergens R.Br., I. scabriusculus subsp. scabriusculus and I. teretifolius, usually have divided leaves.

- 1. Tepals hairy on the whole of the outer surface or at least on the whole of the claw
- 2. Inflorescences usually pendulous, occasionally erect; branchlets with straight or somewhat curved hairs but no coiled hairs present. Involucral bracts glabrous or partially hairy outside; hairs appressed,

2: Inflorescences always erect; branchlets covered with short coiled hairs, sometimes also with long straight hairs. Involucral bracts densely hairy outside; hairs spreading and/or coiled

- 3. Tepals cream or yellow. Mature leaves 20-65 mm long
- 3: Tepals pink. Mature leaves 80–180 mm long
- 4. Leaves 2.5-3 mm wide. Mature tepals > 20 mm long;
- 4: Leaves 1–1.7 mm wide. Mature tepals < 20 mm long; longest
- 1: Tepals with a terminal tuft of hairs, glabrous on all or most of claw
- Branchlets villous. Mature leaves 12–26 mm long, with fine
- 5: Branchlets glabrous or minutely hairy. Mature leaves 22–180 mm long, \pm glabrous or with appressed hairs
 - **6.** Flower heads pendulous. Young branchlets with \pm appressed,
 - 6: Flower heads erect. Young branchlets minutely hairy with coiled hairs (these sometimes restricted to small patches adjacent to axils, with the rest of the stem glabrous), sometimes also with some straighter hairs
 - 7. Stem directly below the inflorescence usually glabrous (although with minute, coiled hairs on young branchlets). Leaves usually 0.7–1 mm wide, rarely up to 1.4 mm wide. Mature cones with a neat, regular outline produced by numerous, tightly packed rows of cone scales

7: Stem directly below the inflorescence with minute, coiled hairs. Leaves 1.3-4 mm wide. Mature cones with an irregular outline resulting from few rows of somewhat protruding cone

Acknowledgements

We are grateful to Rob Davis for collecting this species and taking images for us, Juliet Wege for her support and advice, and Kelly Shepherd for preparing Figure 1.
